A new division has been formed in the British Association which will deal with the social and international relations of science. The association has made much closer contact with the American Association for the Advancement of Science. The number of American visitors this year was a record—more than eighty. The association has been anxious for closer contact, and it will be achieved by lectureships. In one year an eminent American lecturer will come to the British Association and discuss some topic of broad scientific and possibly of social interest, and in the following year a British lecturer will visit America on a similar mission. It has also been felt that the two associations should be closely cognizant of each other's activities. To that end the British Association will elect to honorary membership members of the council and officers of the American association, and the American association will pay a similar compliment.

Marriage After Recovery from Lethargic Encephalitis

An inquest on a woman aged 25, who died in an epileptic fit, has for the first time in this country given practical proof of the danger of marriage to a woman who has suffered from lethargic encephalitis. She suffered from that disease at the age of 11 years but was stated to have made a remarkable recovery under institutional treatment. Her mother alleged that a physician had said that she would be better if married. She married three years ago, but since the birth of a child last September she had been very ill. The physician who had attended her for several years denied that he ever suggested that she would be better married. "No sane medical man would advise marriage in a case like this," he added. Dr. J. M. Webster, director of the West Midland Laboratory of Forensic Science, gave evidence that there was a tendency for patients who had suffered from lethargic encephalitis to get worse after marriage.

Research in Food Storage

Experiments which may revolutionize methods of preserving and storing food are being carried out at the Low Temperature Research Station, Cambridge. Scientists working there for the Department of Scientific and Industrial Research are using radium x-rays and ultraviolet rays in search for the ideal sterilizing agent for meat. It is hoped to evolve a method better than the present cold storage. It is thought that meat might be sterilized by radiation without affecting its quality or appearance. But sufficient is not yet known about the action of radiation on biologic material. A new remarkable line of research—biologic control—is being developed. By means of it certain bacteria would be deliberately allowed to grow, while others would be killed or inhibited. It would thus be possible to alter the flavor of meat at will, just as the cultivation of certain bacteria in cheese creates special flavors of the various types.

The Future of Biochemistry

At the meeting of the British Association a symposium was held in the Chemistry Section under the chairmanship of Sir Frederick Gowland Hopkins, the pioneer of biochemistry in this country. He is 77, a Nobel prize winner and a past president of the Royal Society and the British Association. He has held the chair of biochemistry at Cambridge since 1914.

and announced his approaching retirement. In his address he welcomed the government's decision, on the advice of the Medical Research Council, to endow chemotherapeutic studies in this country on a satisfactory scale. It was just fifty years since he "became a would-be biochemist," and he had followed with deep interest the gradual approach of modern organic chemistry to modern biology and medicine. That approach had been slow, but it had accelerated in recent years. He believed that the advent of so many eminent and enlightened organic chemists in the field of biochemistry was of the happiest augury both for the biologic sciences and for medicine. "As I retire from this field I foresee a possibility which gives me some concern. It is inevitable that the thought of the physiologist will come to deal more and more with the chemical aspects of his science. He and the chemist, organic and physical, are moving toward each other. Does this mean that biochemistry, with the special claims it is making today, will disappear? Will the biochemist be squeezed out of existence between the upper and nether millstones? I hope not. It is my faith that the studies of the dynamics of living tissues now emerging from an embryonic stage are fated to develop a technic which must always be specialized and which will become complete. Its application will call for special training, and it will be the main concern of the future biochemist. He will always be needed as a link between the pure chemist, organic and physical, and the needs of biology and medicine."

The Protection of London Against Air Raids

Though elaborate precautions are being taken against gas attacks on this country, little has so far been done in providing shelters against explosive bombs. In the case of London the difficulty and expense of providing adequate shelter for the population are enormous. A comprehensive scheme, drawn up by the Science Commission of the International Peace Campaign, has been submitted to the government. The commission includes Prof. J. B. S. Haldane, Prof. J. R. Marrack (chemical pathology), Professor Bernal (physics) and leading architects, surveyors and engineers. As the most realistic way of showing how protection could be achieved, an area of London, the borough of St. Pancras, with a population of 136,287, was selected. The report states that the civil population has now become a definite military objective and is not simply the unfortunate recipient of misdirected bombs intended for military targets. It is pointed out that future air raids will be of a far different character from those of the great war, when the total casualties in England were 1,414 killed and 3,416 wounded by about 270 tons of bombs. It is now possible to unload that quantity in about three raids.

The commission recommends the evacuation of children and some of the mothers and the provision of shelters for every one else in such a manner that no one should be more than two or three minutes from the entrance to a shelter. It is proposed that all children up to 14, the mothers of those up to 5, all people over 70, and the sick and infirm be evacuated for the duration of the war to places less liable to attack. To carry this out in St. Pancras would mean leaving 136,287 out of the population of 183,900. It is recommended that a definite area in the country be allocated to each borough. The children up to 3, their mothers and the old people would probably be billeted in existing houses in the country without too much overcrowding. But it would be necessary to provide new accommodation for the school children and those looking after them. Colonies of holiday camp type with educational, sanitary and other facilities should be constructed, each to contain not more than 500 and to be a considerable distance from the next camp, so that no new targets worthy of attack would be created. To provide additional safety the camps should be camouflaged and trench systems constructed in the surrounding country.

Regarding the shelter system, the commission believes a system of tunnels would provide the main solution in St. Pancras. The London clay presents a relatively simple problem for the tunnel engineer. Parts of the present tube railway, lying at a depth of 60 feet or more, can be easily adapted for the purpose of shelter, but the running of trains should not be seriously interfered with and therefore only passages and platforms should be used. The proposed shelters are to be tunnels in the London clay, 50 feet below the surface, of inverted U section and lined with steel. They are to be 6 feet 6 inches wide and 7 feet 6 inches high, with a row of seats along each side and a gangway in the middle. Electric light, air filtration plant, gas locks, hot and cold water, decontamination and dressing rooms, chemical closets and facilities for dealing with minor casualties are to be provided. Access is to be by stairways, staggered to prevent the entrance of missiles.

The Experimental Aspect of the Paravitaminoses

A paper based on experimental research was read by Dr. Georges Mouriquand at the June 14 meeting of the Académie de médecine of Paris. He stated that the study of avitaminoses, whether outspoken or latent in their clinical manifestations, had led to his study of the paravitaminoses during the past twenty-five years. This term is employed in the sense in which Fournier used that of parasyphilis for such diseases as tabes and dementia paralytica, which, although of syphilitic origin, failed to show specific tissue changes regarded as typical for this type of infection. The specific lesions of syphilis are amenable to treatment but this is not true of those of the parasyphilitic conditions. The evolution of the definitely recognized vitamin-deficiency conditions, i. e., of the various avitaminoses, is the same as that from syphilis to parasyphilis. An avitaminosis after having given rise to lesions which can be considered specific for the particular type of avitaminosis is amenable to treatment with the vitamin that is lacking, but this apparent recovery is followed by lesions which are more or less resistant even though the administration of the particular vitamin is continued. One now enters the domain of aspecific lesions to which the term paravitaminosis can be applied. Thus one can speak of a paravitaminosis A, B or D but the author limited his paper to the discussion of acute and chronic paravitaminosis C. An acute avitaminosis C passes through a eutrophic and a dystrophic stage. During the course of the former the typical lesions of scorbutus without general dystrophy are observed. In this stage the use of ascorbic acid during a period of a few days is followed by healing of the lesions and reestablishment of the normal equilibrium of nutrition. From twenty to twenty-four days later, sometimes sooner, a persistent diarrhea appears accompanied by anorexia and a loss of weight. This is the second or dystrophic stage. Even at this period the diarrhea can be checked by ascorbic acid, but, although the appetite returns, the signs of defective nutrition increase from day to day. The animal, although showing marked evidence of inanition, continues to eat but assimilation has come to a standstill. No matter how much ascorbic acid is given, the inanition persists, i. e., a new form of dystrophy has supervened and one can speak of an acute paravitaminosis of the athreptic type.

The author's study of chronic avitaminosis C has been of special interest in clearing up the question of paravitaminosis C.

It is not difficult to produce a chronic scorbutus in guinea pigs. Toward the thirty-fifth to fortieth day, lesions appear which are characterized by edemas and hemorrhages, which at times assume huge proportions but which respond promptly to the action of ascorbic acid. If, however, no such treatment is given, the lesions tend to regress and even disappear; but

as sequels a marked muscular retraction with pseudo-ankylosis, especially of the hind legs of the animal, appear. Radiography toward the seventieth or eightieth day reveals progressive osseous changes in the form of decalcification of the epiphyses and a marked periostitis. At this time there is a transition from the stage of avitaminosis to that of a paravitaminosis, in which the administration of ascorbic acid has no influence on the osseous lesions, which are now in the aspecific stage. If one has not had occasion to follow the bone and muscular changes from the onset, their relation to an avitaminosis may escape detection.

Dr. Mouriquand stated that no clinical observations had as yet been made as to such paravitaminoses.

Reopening of the Palace of Discovery

One of the most interesting and popular features of last year's Paris Exposition was the scientific exhibit arranged under the supervision of Dr. Pasteur Vallery-Radot, a grandson of Louis Pasteur. This exhibit was reopened to the public July 11 by Mr. Zay, minister of public education. The object of the exhibit in the Palace of Discovery is to familiarize the public with the advances that have been made in all branches of science during the last 150 years. Close to the entrance is an enormous apparatus for generating static electricity constructed by Professor Joliot, son-in-law of the late Mme. Curie. The discoveries of the latter and of Langevin on the piezo-electric vibrations of quartz and on ultra sounds have been utilized in a minute organ capable of giving forth a range of combinations of sounds beyond the imagination of an ordinary individual. A planetarium showing the mechanism of eclipses is an instructive feature. The television exhibit includes all the latest discoveries in this field. The same is true of that of the physics display, including demonstrations of atomic and molecular composition of matter. The medical and surgical sections include a series of charts, amplified by charts and by photographs of bacteriologists of all countries who have become famous as the result of their contributions to this field. In the surgical section the different methods of blood transfusions are illustrated with the aid of wax figures of donors and recipients, showing how the different types of apparatus are employed. The anesthesia section gives the lay public an idea of the progress made during recent years in this special field. Modern medicine can look with pride on the contributions which it has made to the prolongation of life as reflected in its exhibits in the Palace of Discovery.

Plaque in Honor of Professor Brown-Séquard Dedicated at Nice

During the recent Congrès des sociétés savantes, a plaque in commemoration of the work of the late Professor Brown-Séquard was placed in the lobby of the Centre Universitaire at Nice. Before Brown-Séquard's election as professor of experimental and comparative pathology in the University of Paris, he had been professor of pathology of the nervous system at Harvard University and subsequently a member of the attending staff of the Paralyzed and Epileptic Hospital in London. He is perhaps best known for the paper published in France in 1850 on decussation of the sensory fibers in the spinal cord to explain the syndrome to which the term Brown-Séquard type of hemiplegia has since then been constantly applied. His studies on the function of the sympathetic nervous system were published in Philadelphia in 1852, and his contributions concerning the part played by the endocrine glands in physiology and clinical medicine laid the foundation for present day endocrinology.

Birth Rate Continues to Decline

According to the most recent statistics, 274,122 marriages took place in France in 1937, as compared to 350,000 in 1930. There has been a similar decrease in the number of births since

1930. In that year there were 749,953 births; two years later the number rose to 772,246, but in 1937 it dropped to 616,863. In 1930 there were 100,000 more births than deaths, while in 1937 the number of births exceeded the number of deaths by only 12,000.

Dr. Clovis Vincent Appointed Professor of Neurosurgery

As stated in a previous letter, a department of neurosurgery has been organized at the Faculté de médecine (medical school of the University of Paris). Dr. Clovis Vincent was appointed head of this department August 1 and will begin his courses at the opening of the fall session of the school.

BERLIN

(From Our Regular Correspondent)

Aug. 8, 1938.

The Exclusion of Jewish Physicians

On August 3 a new, fourth amendment to the Nuremberg racial laws was made public. The effect of its enforcement will be to exclude Jewish physicians from the medical profession. On September 30 the licenses (approbationen) of all Jewish physicians become null. From this date a Jewish doctor will not be permitted to attend a patient of German blood. Nor will any whose license is revoked by this ordinance be permitted to practice as a so-called heilpraktiker (a term which in the last analysis signifies "quack"); as the official text reads, he cannot thus "attempt to circumvent the law."

Dr. Grote, director of the association of panel practitioners, has contributed to the *Voelkischer Beobachter* an interesting statistical report on Jewish practitioners in Germany. At the time of the Nazi accession to power in 1933 there were within the reich a total of 6,480 Jewish physicians; included in this number were Jewish hybrids and doctors of Jewish affinity. There were then about 50,000 physicians in Germany, of which number the group classified as Jewish comprised some 13 per cent. In June 1937 there were still 4,220 Jewish physicians in the reich, 3,748 of whom held valid licenses and were engaged in practice. At the time of the Nazi revolution the so-called "alienization" of the profession had been greatest in Berlin; from 70 to 80 per cent of all physicians in that city were Jews. Even after the first "purge" (the term is Dr. Grote's) more than one half of Berlin doctors were Jews, 3,423 Jews in a total 6,558 doctors. In July 1938 there were still 1,561 Jews among the 6,949 physicians of Berlin, the percentage of Jews having declined to 22.4. Among the 2,973 panel practitioners in Berlin in July there were still 816 (27.4 per cent) Jews. The example of Berlin demonstrates, according to Dr. Grote, that previous legislation has not resulted in definitive solution of the problem of the exclusion of Jews in the medical profession, so vitally important to the nation. After October 1, Jewish doctors will be granted special permission to practice but only in communities in which the Jewish population is highly concentrated, as in Berlin. The new law also will, in effect, strengthen the supreme authority of the national fuhrer of physicians over all medical affairs.

The mentioned exceptional permission to remain in practice which will be granted to certain Jewish doctors will not be tantamount to a restoration of the regular license. It will be rather of the nature of a temporary, readily revocable permit to practice medicine under certain specified conditions. A Jew who holds such a permit must, excepting in the case of his wife and legitimate children, restrict his practice to Jewish patients. Violations of this provision, whether intentional or inadvertent, are to be punishable by imprisonment for not more than one year, by fine or by both. Former front line combatants in the World War who are deprived of their licenses by the new law will be granted temporary compensation by the national chamber of physicians, on the basis of need and merit. Further clauses

concern the premature termination of service contracts, leases and so on, necessitated by the new legislation.

According to authoritative report, the organized medical profession will assist Jewish doctors to obtain reeducation in other fields. This movement will receive adequate financial support; further details with regard to it are not yet available.

On the basis of a far-reaching decision of the national bureau of insurance, Jewish hospitals are forbidden to treat non-Jewish sick insurance club patients. In explanation of this measure, it is stated that treatment of non-Jews in a Jewish-controlled hospital provides opportunities for just those contacts between German citizens and Jews which are to be avoided as much as possible.

Determination of Alcohol Content of the Blood

The national fuehrer of the schutzstaffel and the chief of German police have issued a decree with regard to forensic determination of the alcohol content of the blood. The new regulations are based on the aggregate of experience with this problem and will be uniform for the entire country. Only tests the efficacy of which has been proved by experts will be applied. The blood tests will be made in cases wherein establishment of intoxication has an important bearing on the criminal culpability of a suspected person. Likewise, other persons are submitted to the test if intoxication must be established, because it is the result of or clue to a criminal offense committed on one of these persons. Since obtaining the blood specimen can be legally done only by a physician and since the procedure is altogether harmless, it may be performed even without the consent of the person. In traffic accident cases the incontestable determination of the degree of intoxication of all participants, including the victims, is of the utmost importance. Accordingly, all participants in an accident, not only automobile drivers but pedestrians as well, may be submitted to the blood tests if circumstances so warrant. As a precautionary measure the blood test may be made of any person engaged in driving a vehicle or who contemplates driving a vehicle and whose fitness to drive is questioned because of suspected intoxication. Physical examination must be made without delay as soon as possible after the occurrence in question, in order to establish with maximal accuracy the degree of inebriety or sobriety, as the case may be. The blood specimen should be taken within one and one-half hours after ingestion of the alcohol. The foregoing provisions are enforced by all federal and local police authorities within the German reich.

Study of Progressive Muscular Dystrophy

The problem whether there is a uniform hereditary transmission of progressive muscular dystrophy was investigated by Drs. Kostakow and Bodarwé at the Medical Clinic of Bonn University. They arrived at the following conclusions after a study of the genealogies of six familial groups in which progressive muscular dystrophy had been present. The disorder is always based on heredity. Its pathogenesis is traceable to mutations within the sum of hereditary factors in the ascendancy. Its further heritability is not uniformly independent of the fact that in addition to the dominant genes there are also recessive genes which may lead to manifestation of the disease. The investigations assume the existence of at least two forms of dystrophy which differ genotypically and that these correspond to the infantile and juvenile types and are present in kindred. In two of the six mentioned groups a hereditary sex-linked transmission was determined and in the other four simple recessive transmissions. In one group a consanguineous marriage had occurred; the authors emphasize this circumstance as an important factor in the manifestation of muscular dystrophy through the recessive predisposition. The four groups in which simple recessive hereditary predisposition was determined all resided within a circumscribed rural

area. The group in which sex-linked transmission was established presented a predominance of the infantile type of progressive muscular dystrophy with pseudohypertrophy, whereas the simple recessive transmission groups presented both infantile and juvenile types. It was noted that, surprisingly enough, the cause of death in each case had been some disorder of the respiratory organs.

Measures for the Abolishment of Sterility in Women

The interested ministries, the panel practitioners' association and the sick insurance clubs have instituted concerted measures destined to reduce the incidence of sterility in women to the lowest possible minimum. In certain instances, sterility of married women may be considered a general illness even if the condition is not linked to significant lesions or lack of working capacity. This concept obtains if there is a possibility of abolishing the condition and if the fertility of the patient would best serve the public good. If these prerequisites are fulfilled, the insurance clubs handle the necessary arrangements. The confidential medical advisers of the clubs make the recommendations in each case. The expert opinion of these officers contains data with regard to the curability of the sterility, possible contraindication of surgical measures on the basis of health, and the condition of the husband with regard to procreation. Formerly, arrangements in such cases were under jurisdiction of the national minister of labor, but now the minister of the interior is also a participant. The last named official has decreed, as supplementary to previous legislation, that pertinent genealogic data should be acquired by the officers of the hygienic centers. The eugenic standards must be at least as exacting as those required of candidates for the state marriage subsidies. Free examinations of supposedly sterile women are made at the centers. Only women of German or related blood are eligible.

In the wake of all this ministerial regulation the panel practitioners' association of Germany has entered into agreements with a number of the insurance clubs relative to the mentioned examinations for sterility. The expert should decide in addition to the questions already mentioned the matter of the most promising and at the same time most economical procedures to be followed. Special medical services not usually envisaged in the contracts between the sick insurance clubs and the medical organization are paid for even if the examination is not followed by operative or other treatment. The clubs also assume the costs of the genealogic investigation. If all the prerequisites are satisfied, the cost of treatment is shouldered by the club in question.

Cancer and Occupation

The National Anticancer Commission undertook a questionnaire survey with regard to the occupation of 1,250 male cancer patients. A distinction was made between skilled workers and unskilled workers. Dr. Hellmut Haubold, cancer specialist of the National Health Bureau, reports the results in the *Reichs-Gesundheitsblatt*. Men of uncertain occupation were so listed and in the definitive classification this group was reckoned among the unskilled workers. But despite this precaution the survey showed that a vast majority, 75.8 per cent of the men, belonged to the skilled worker class. Of these 951 skilled workers the largest individual group (227 men) was that of the civil servants. In second place were 150 farmers, and in third place 139 workers in the metallurgic and related industries, including workers in the production of iron and steel and workers in wrought metals; next were 101 workers in the building trades. The largest class among the unskilled workers appertained to the iron, steel and other metal industries; second in rank were the unskilled farm laborers. The proportion of skilled workers, who comprised more than three fourths of the subjects, was explained as a logical result

of the membership in an occupational group and cancer incidence at a particular age level, since among the older group the proportion of skilled workers tends to exceed the proportion of the unskilled. Among the 1,250 men, only 110 skilled and seventy-one unskilled workers were over 70 years of age, namely but 14.4 per cent of the total. Moreover, it was found that the group most threatened by cancer lay between the ages of 40 and 65 (almost 60 per cent of the men were between these ages). This formidable incidence of cancer in middle age represents an important national menace, for cancer is by no means only a disease of old age. This is one more reason why the campaign against cancer should go forward intensely.

The Sphere of Application of Tomography

The question Under what conditions may tomography be substituted for the usual roentgenography? was recently discussed by Dr. H. J. Teschendorf before the Frankfort Medical Society. Experience to date has shown tomography (in Germany known as "roentgenschnittverfahren," roentgen-layer method) to be of indispensable value in the determination of tuberculous and bronchiectatic cavities and pulmonary abscesses. Tomographic examination of the lungs following thoracoplasty represents a particularly important application of the newer technic, since a sufficiently clear picture of the extent of the cavity and accordingly of the degree of success achieved by the intervention is but rarely provided by means of the ordinary roentgenogram. Tomography, however, can never completely supplant the usual roentgenography of the lung. The tomographic demonstration is superior to the older methods only in the fields of the sternum and the sternoclavicular joint. These parts cannot be accurately visualized by ordinary roentgenography. How widely tomography may be utilized as an aid in the detection of changes in the vertebral column and cranium, further investigation will disclose.

POLAND

(From Our Regular Correspondent)

Aug. 14, 1938.

Resolution Concerning Aryans

Some members of the Association of Physicians of Poland who are adherents of racial theories managed at a meeting of the association in December 1937 to pass a resolution forbidding doctors of Jewish origin to the third generation to be members of the association. This paragraph was strongly opposed by the democratic physicians, who in many districts of Poland have formed the majority in the branch associations. The associations of those districts have broken with the board in Warsaw and consequently the association is now divided into two parties. Only the adherents of the racial theories have remained followers of the present board. The latter had to create new branches of the association in those districts of Poland in which a strong opposition on the part of the democratic physicians was encountered. This internal dissension has weakened the authority and activity of the association, which formerly cared for public health and defended the dignity of the medical profession.

Influence of Pancreatic Tumors on Urine from Right Kidney

Dr. Markert reported six cases of cancer in the cauda pancreatis in which a decrease of the secretional function of the left kidney was noticed. Thus the diuresis, the secretion of urea, chlorates and the dye introduced by intravenous injection were remarkably decreased. That phenomenon is probably caused by a reflex produced by excitation of the sympathetic nerves by the infiltrated retroperitoneal lymphatic glands or by the infiltrated capsule of the left kidney. This decrease of the secretion of the left kidney in case of tumor of the cauda pancreatis might suggest an erroneous diagnosis.

The Congress of Polish Hygienists

The eleventh Congress of Polish Hygienists took place in Lublin July 29-30 on the fortieth anniversary of the Polish Hygienic Society. The meeting was devoted to health problems of villages. On account of the bad state of health in villages, the congress appealed to the government to increase the work of putting the hygiene of the village on a higher level, by supplying the country folk with medical aid. Poland is an agricultural country.

Study of Causes of Pericarditis

In the Institute of Pathologic Anatomy of the Cracow University, postmortem examinations concerning the causes of pericarditis have been made by Dr. Hassmann. The material consisted of 9,739 cases, among which inflammatory lesions or their residuums in the pericardium were found in 463. Statistical data on the etiology showed the following percentages: rheumatism 19.4, tuberculosis 18.7, septic suppuration 14.6, pneumonia 12.7, purulent pleuritis 9, tumors of the mediastinum 6, diseases of the kidneys 4.5 and myocardial infarct 2.

Research on Cardiac Arrhythmia

At the session of the medical department of the Polish Academy of Science, May 20, Dr. Hrom of the clinic of Warsaw University read a paper based on 1,300 cases of arrhythmia observed in the last nine years and in which 1,765 electrocardiographic records were made. These researches confirmed the knowledge that cardiac arrhythmia can be caused not only by cardiovascular disorders but by physical effort, tobacco or coffee, digitalis and diseases of other organs. It appeared that atrioventricular dissociation is more often caused by diffuse lesions of the myocardium than by circumscribed lesions. It has also been proved that auricular fibrillation often disappears through a transitory period of auricular flutter. To distinguish extrasystoles of functional origin from those caused by organic lesions of the myocardium, the author has noticed that in the latter case the effort test caused extrasystoles of a different electrocardiographic shape and in different directions, while in functional cases all the electrocardiographic records of the extrasystoles were of the same shape and direction. Cardiac arrhythmia occurred most frequently in women with thyrotoxicosis and in the period of the menopause. It was noticed that auricular fibrillation was more frequent in women than in men, while disorders of conduction occurred more frequently in men.

Marriages

WILLIAM CLINTON WHITE, Washington, D. C., to Miss Frances Evelyn Daniel of Greenville, S. C., recently.

CHARLTON GILMORE HOLLAND, Danville, Va., to Miss Louise Fraser Beckwith at Petersburg, August 6.

HAROLD LAWTON ROGERS, Tuscaloosa, Ala., to Miss Frances Love McKenzie of Fulton, Ky., in July.

HENRY L. SKINNER, Battle Ground, Wash., to Miss Enid Carson of Vancouver, B. C., August 7.

JOHN WALLACE LYNCH, Seaford, Del., to Miss Ruth Marie Cooper of Greensboro, Md., April 17.

JAMES MAXEY DELL to Mrs. Rose H. Eddins, both of Gainesville, Fla., in Baltimore in July.

FRANKLIN McELHENY, Atlanta, Ga., to Miss Helen Porter of Greenwood, S. C., June 29.

HUGH D. DONAHUE, Boston, to Miss Rose Fitzgerald of Dorchester, Mass., recently.

NOEL CLARK MELLEN, Pensacola, Fla., to Miss Lorrain Bader of St. Louis, July 2.

JOHN M. DORSEY to Mrs. Charlotte Burns Hoefler, both of Chicago, June 29.

Deaths

Philip Marvel ☉ Princeton, N. J., died suddenly September 6 at Bushkill, Pa., aged 81. Dr. Marvel was born in Kent County, Delaware, Sept. 15, 1856. He graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1884 and practiced for many years at Atlantic City. During his long active career Dr. Marvel served the American Medical Association in many capacities. In 1900-1901 he was third vice president and in 1902 was a member of the House of Delegates. In 1904 he was elected a trustee, serving until 1910, and again from 1911 to 1920. He was again a member of the House of Delegates in 1923, 1928-1930, 1934 and at the special session of 1935. In 1925 he was elected vice president for the second time. Dr. Marvel was president of the Medical Society of New Jersey in the year 1916-1917 and was made an honorary member at the annual meeting in 1935. He was a founder of the New Jersey Tuberculosis League, an Affiliate Fellow of the American Medical Association, a fellow of the American College of Physicians and a member of the American Clinical and Climatological Association. At frequent meetings of the Association in Atlantic City he aided greatly in making arrangements and in coordinating activities. The success and welfare of the organization were his first consideration.

Edwin Beer ☉ New York; Columbia University College of Physicians and Surgeons, New York, 1899; member of the American Surgical Association, and American Urological Association; member and past president of the Clinical Society of Genito-Urinary Surgeons; fellow of the American College of Surgeons; served during the World War; attending surgeon to the Mount Sinai Hospital and consulting surgeon to the Bellevue Hospital; in 1936 received a gold key of merit from the American Congress of Physical Therapy for his work on the treatment of tumors of the bladder; author of articles on gallstones, intestinal diseases, tumors of the bladder and surgical diseases of the kidney; aged 62; died, August 13.

William Oliver Spencer, Winston-Salem, N. C.; Jefferson Medical College of Philadelphia, 1891; member of the Medical Society of the State of North Carolina; formerly member of the state board of health; at one time health officer of Winston-Salem and Forsyth County; former president of the Forsyth County Medical Society and vice president of the Medical Society of the State of North Carolina; on the staffs of the City Memorial and North Carolina Baptist hospitals; aged 75; died, June 30, of diabetes mellitus.

Abram Tucker Kerr ☉ Ithaca, N. Y.; University of Buffalo School of Medicine, 1897; assistant in histology and pathology, 1894-1897, acting and adjunct professor of anatomy, 1898-1900, at his alma mater; assistant professor of anatomy, 1900-1904, professor of anatomy and secretary since 1904, Cornell University, acting professor of hygiene, 1920-1922, and acting professor and director of hygiene since 1935; member of the American Association of Anatomists; aged 65; died, August 15, of heart disease.

David R. Clark ☉ Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1895; professor of psychiatry at the Wayne University College of Medicine; member of the American Psychiatric Association; at various times on the staffs of the Receiving, Providence, Highland Park (Mich.) and the Florence Crittenton hospitals; aged 64; medical director of St. Joseph's Retreat, Dearborn, Mich., where he died, July 3, of carcinoma of the head of the pancreas.

Louis Shepard De Forest, New Haven, Conn.; Thüringische Landesuniversität Medizinische Fakultät, Jena, Thuringia, Germany, 1885; on the faculty of Yale University School of Medicine as clinical assistant in medicine 1890-1891, instructor in medicine 1891-1892, assistant professor of medicine 1892-1895 and clinical professor of medicine 1895-1899; aged 81; died, August 4, of arteriosclerosis.

Thomas A. Copeland, Athens, Ohio; College of Medicine and Surgery, Chicago, 1887; member of the Ohio State Medical Association; for many years secretary of the Athens County Medical Society; served on the local examining board during the World War; aged 73; died, July 9, of cerebral arteriosclerosis and hypertension.

Clyde Lowe Casey, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1913; member of the Illinois State Medical Society; served during the World War; aged 49; died, July 19, in Marion, Ill., of chronic lymphatic leukemia.

Arthur Ivan Laughlin ☉ Clarksville, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor,

1903; bank president; member of the school board; for many years secretary of a district board of education; aged 59; died, June 20, of angina pectoris.

James Elston Adams, Cushing, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1917; member of the Oklahoma State Medical Association; on the staff of the Masonic Hospital; aged 42; died, May 31, of injuries received in an automobile accident.

Samuel Morton Creswell ☉ Tacoma, Wash.; Rush Medical College, Chicago, 1926; past president of the Washington State Public Health Association; on the staff of the Tacoma General Hospital; health officer; aged 38; was killed, July 8, in an automobile accident.

William Matthews Bigham, Memphis, Tenn.; Missouri Medical College, St. Louis, 1881; member of the Tennessee State Medical Association; on the staff of St. Joseph's Hospital; aged 78; died, July 8, in the Gartley-Ramsay Hospital of uremia and pyelitis.

John Joseph Fralinger, Philadelphia; Jefferson Medical College of Philadelphia, 1912; member of the Medical Society of the State of Pennsylvania; also a pharmacist; on the staff of St. Agnes' Hospital; aged 55; died, June 21, of chronic myocarditis.

Orton Horace Clark, Pasadena, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; served during the World War; aged 74; died, July 26, in the University Hospital, Ann Arbor, Mich., of bronchopneumonia.

Frank Nott Danforth ☉ Texas City, Texas; University of Texas School of Medicine, Galveston, 1905; health officer; formerly member of the school board; aged 55; died, July 16, in the John Sealy Hospital, Galveston, of coronary thrombosis.

Nelson Kaufman Fromm ☉ Albany, N. Y.; Albany Medical College, 1908; associate professor of neurology at his alma mater; served during the World War; on the staff of the Albany Hospital; aged 56; died, June 22, of coronary disease.

Scott Kenyon Gray, Watervliet, N. Y.; Barnes Medical College, St. Louis, 1905; served during the World War; aged 61; on the staff of the Troy Hospital, where he died, June 29, of arteriosclerotic heart disease and diabetes mellitus.

Roswell Kelsey Palmerton, Deposit, N. Y.; College of Physicians and Surgeons, Baltimore, 1881; member of the Medical Society of the State of New York; formerly bank president; aged 81; died, June 7, of chronic nephritis.

George Moore Braden, Scotts, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1883; member of the Michigan State Medical Society; aged 81; died, July 10, of chronic myocarditis and arteriosclerosis.

Bruce Keifer, Paden City, W. Va.; Maryland Medical College, Baltimore, 1900; formerly mayor; served during the World War; aged 63; was found dead, June 12, of burns received when he fell asleep with a burning cigaret.

Simrall Anderson, Louisville, Ky.; University of Louisville (Ky.) Medical Department, 1901; served during the World War; on the staff of the SS. Mary and Elizabeth Hospital; aged 58; died, July 7, of carcinoma of the liver.

Forrest Hartley Badger ☉ Winthrop, Maine; Medical School of Maine, Portland, 1894; past president of the Kennebec County Medical Society; formerly superintendent of schools; aged 68; died, July 13, of coronary thrombosis.

James Warren Brewer, Dayton, Ohio; Ensworth Medical College, St. Joseph, Mo., 1908; veteran of the Spanish-American War; formerly on the staff of the Veterans Administration Facility; aged 60; died, June 5.

James Lyons Biggar, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1903; served in the Boer and World wars; national commissioner of the Canadian Red Cross Society; aged 60; died, June 2.

Daniel Emanuel Kauffman ☉ St. Louis; St. Louis University School of Medicine, 1924; served during the World War; aged 40; on the staff of St. Mary's Hospital, where he died, June 16, of uremia and nephritis.

Achilli Ubaldo Opipari, Pittsburgh; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1906; member of the Medical Society of the State of Pennsylvania; aged 63; died, June 30, of cerebral hemorrhage.

Patrick Coote, Quebec, Que., Canada; M.B., Laval University Faculty of Medicine, Quebec, 1882, and M.D., 1884; emeritus professor of clinical ophthalmology and otology at his alma mater; aged 75; died, June 20.

Edward Cary Ambler, Roanoke, Va.; University of Virginia Department of Medicine, 1897; member of the Medical Society of Virginia; past president of the Roanoke Academy of Medicine; aged 68; died, July 11.

Frederic Rudolph Kruger * Galveston, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1903; aged 59; died, June 8, in the John Sealy Hospital of pneumonia following a gallbladder operation.

Henry M. Freas, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1885; member of the Medical Society of the State of Pennsylvania; aged 78; died, June 28, of chronic myocarditis.

Elmer Ellsworth McAdoo, Ligonier, Pa.; Jefferson Medical College of Philadelphia, 1891; formerly member of the state legislature, and member of the school board; aged 75; died, June 22, of coronary occlusion.

Lester Levyn * Buffalo; Maryland Medical College, Baltimore, 1909; fellow of the American College of Physicians; member of the Radiological Society of North America; aged 50; died, June 24, of leukemia.

James F. O'Leary, Hartford, Conn.; University of Buffalo School of Medicine, 1897; formerly police commissioner; aged 64; died, June 29, in the St. Francis Hospital of hypertension and cerebral hemorrhage.

Morris Manuta, Johnstown, Pa.; Medical College of Virginia, Richmond, 1937; aged 25; intern at the Conemaugh Valley Memorial Hospital, where he died, June 14, following an operation for appendicitis.

Harry Hambleton Stewart * Pottsville, Pa.; Baltimore Medical College, 1907; served during the World War; aged 68; on the staff of the Lemos B. Warne Hospital, where he died, June 17, of typhoid.

Clarence C. Tolleson, Long Beach, Calif.; University of Maryland School of Medicine, Baltimore, 1914; on the staff of the Community Hospital; aged 47; died, June 12, in a hospital at Hermosa Beach.

Alvah Cochran Cummings * Newton, Mass.; Harvard University Medical School, Boston, 1901; for many years city physician; aged 64; died, July 11, at Grand Lake Stream, Maine, of heart disease.

Arthur Gamble Hilliard, Rochester, N. Y.; New York Medical College and Flower Hospital, New York, 1914; served during the World War; aged 50; died, June 19, of coronary thrombosis.

Warren Clifford Batroff * Philadelphia; Medico-Chirurgical College of Philadelphia, 1903; veteran of the Spanish-American War; aged 58; died, June 20, in Merion Station, Pa.

Luigi Balducci, Rochester, N. Y., Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1908; aged 55; died, May 2, of carcinoma of the prostate and secondary anemia.

Jose I. Abuel y Villasenor * Manila, P. I.; University of the Philippines College of Medicine, Manila, 1918; assistant professor of surgery at his alma mater; aged 45; died, May 7.

Quinn Worth Gard * Seguin, Texas; Washington University School of Medicine, St. Louis, 1928; on the staff of the Seguin Hospital; aged 35; died, July 20, of coronary disease.

George O. Davis, Madison, Fla.; College of Physicians and Surgeons, Baltimore, 1903; member of the Florida Medical Association; aged 62; died, July 6, of coronary thrombosis.

James Walter Myer, Pelham, N. Y.; Harvard University Medical School, Boston, 1903; aged 65; died, June 11, in the Mount Vernon (N. Y.) Hospital of coronary thrombosis.

Edward E. Rowell Sr., Stamford, Conn.; New York Homeopathic Medical College, 1877; aged 84; died, June 27, of cerebral thrombosis, arteriosclerosis and chronic nephritis.

Lemuel Caro * New Rochelle, N. Y.; Cornell University Medical College, New York, 1921; aged 41; was killed, July 22, in an airplane accident near Bucharest, Rumania.

Henry Smith Turrill * Kent, Conn.; Yale University School of Medicine, New Haven, 1910; for many years health officer; aged 53; died, June 7, of arteriosclerosis.

James Lawrence Cornitcher, Danville, Va.; Meharry Medical College, Nashville, Tenn., 1929; aged 39; died, July 7, in the Providence Hospital of intestinal obstruction.

Morris Karl Diner, New York; University and Bellevue Hospital Medical College, New York, 1937; intern at the Morristown City Hospital; aged 23; died, June 9.

Edgar Sargent Ferris, Columbus, Ohio; Miami Medical College, Cincinnati, 1888; aged 72; died, July 6, of acute yellow atrophy of the liver and chronic myocarditis.

Thomas Walter Witt, Lake City, Fla.; Atlanta Medical College, 1915; formerly secretary of the Columbia County Medical Society; aged 46; died, June 8.

Ervin S. Thompson, Smoaks, S. C.; Medical College of the State of South Carolina, Charleston, 1910; aged 58; died, June 27, in a hospital at Walterboro.

Samuel H. Vehslage, Scarsdale, N. Y.; New York Homeopathic Medical College, 1879; aged 89; died, June 18, of cerebral arteriosclerosis and myocarditis.

Franklin Henderson Doud, Lysander, N. Y.; University of Michigan Homeopathic Medical School, Ann Arbor, 1893; health officer; aged 74; died, June 5.

Abraham Malisoff, Woodridge, N. Y.; Cornell University Medical College, New York, 1900; aged 61; died, June 18, of gastric carcinoma and heart disease.

John Rumbaugh Shetter, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1895; aged 77; died, June 18, of coronary occlusion.

Henry A. Smith, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1875; aged 89; died, June 18, of myocardial degeneration.

James Winter Brown, Stoneboro, Pa.; University of Oklahoma School of Medicine, Oklahoma City, 1914; aged 52; died, June 29, of tumor of the brain.

William Rich Collett, Philadelphia; Jefferson Medical College of Philadelphia, 1931; on the staff of the Friends Hospital; aged 31; died, June 18.

Alexander Joseph Burkholder, Staunton, Va.; Baltimore University School of Medicine, 1902; aged 77; died, July 15, of myocarditis and heart block.

Walter S. Spears, Ardmore, Okla.; Fort Worth School of Medicine, Medical Department of Texas Christian University, 1902; aged 69; died in June.

Hughlett Hardcastle, Easton, Md.; University of Maryland School of Medicine, Baltimore, 1895; aged 76; died, June 18, in the Emergency Hospital.

Abraham Shaw, Philadelphia; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1899; aged 64; died, June 29, of cerebral hemorrhage.

William Harter Everhard, Medford, Ore.; Rush Medical College, Chicago, 1880; aged 81; died, July 17, of carcinoma of the lungs and prostate.

William J. Bowen, Mount Pleasant, S. C.; Medical College of South Carolina, Charleston, 1893; aged 69; died, July 14, of cardiac dilatation.

David M. Buck, Jr., Asheville, N. C.; Medical College of Virginia, Richmond, 1925; aged 35; was killed, June 19, in an airplane accident.

Carl L. Cheney, De Kalb, Ill.; Chicago Homeopathic Medical College, 1902; aged 63; died, July 9, in the Public Hospital, of heart disease.

Luther A. Donoho, Wayland, Ky.; University of Tennessee Medical Department, Nashville, 1907; aged 54; died, July 2, in Martin, Tenn.

Lawrence H. Smith * Hazleton, Pa.; College of Physicians and Surgeons, Baltimore, 1883; aged 78; died, June 20, of pneumonia.

George Conrad Snyder, San Francisco; Ohio Medical University, Columbus, 1901; aged 72; died, June 16, in Philadelphia.

John Wesley Porter, New Park, Pa.; University of Maryland School of Medicine, Baltimore, 1895; aged 72; died, June 26.

William Franklin Smith, Decherd, Tenn.; Vanderbilt University School of Medicine, Nashville, 1898; aged 70; died, June 18.

Rafael Jacobsen, Havana, Cuba; University of Pennsylvania School of Medicine, Philadelphia, 1913; aged 47; died, June 4.

Walter Andrew Reichle * Spokane, Wash.; Creighton University School of Medicine, Omaha, 1924; aged 42; died, June 4.

James P. Drafts, Leesville, S. C.; University of Tennessee Medical Department, Nashville, 1899; aged 62; died, July 1.

Gideon Meredith Freeman, Los Angeles; Cooper Medical College, San Francisco, 1903; aged 58; died, June 15.

Everett Herschel Winter, Hollis, N. Y.; Long Island College Hospital, Brooklyn, 1899; aged 64; died, June 27.

Wiley Claude Crump, Lumberton, N. C.; Meharry Medical College, Nashville, Tenn., 1926; aged 42; died, June 20.

Jacob S. Krebs, Herndon, Pa.; College of Physicians and Surgeons, Baltimore, 1884; aged 76; died, June 10.

William Jay Dugan, Paris, Ill.; Missouri Medical College, St. Louis, 1899; aged 64; died, July 12.

Correspondence

SOLITARY TUBERCULOMA OF THE LIVER

To the Editor:—In an article which appeared in *THE JOURNAL* August 6, Herrell and Simpson report what they consider to be a case of solitary tuberculoma of the liver with an exceedingly rare "pathologic lesion." It is highly questionable whether the authors are justified in ascribing the cause of the condition to the tubercle bacillus on the weak evidence they present. The clinical course and laboratory data are not typical of tuberculosis, no mention is made of tests with tuberculin, and no evidence of tuberculosis elsewhere was found. Under these circumstances one cannot make a diagnosis of tuberculosis simply because of the presence of small granulomas and giant cells in the lesion. Many other conditions may give rise to similar granulomatous changes in the liver, among which may be mentioned chronic low grade infection with a mixture of bacteria, actinomycosis or other fungous infections, glanders, tularemia and undulant fever.

It would seem that before one could accept a diagnosis of the rare condition called tuberculoma of the liver it would be necessary to prove the diagnosis by the demonstration of tubercle bacilli in the lesion by tinctorial or cultural methods.

HOBART A. REIMANN, M.D., Philadelphia.

AMPLIFICATION OF HEART AND LUNG SOUNDS

To the Editor:—The sweeping statement of Douglas Macfarlan (*THE JOURNAL*, June 18, p. 2069) that "amplification of heart and lung sounds is neither practical, nor desirable, nor needed for the physician with normal hearing" should not remain unchallenged.

Amplification has been made practical by several devices described in the literature:

- Beruti, J. A.: *Semana méd.* 30: 829, 1923.
Duchosal, P., and Luthi, R.: *Arch. méd. d. mal. du cœur* 22: 806, 1929.
Sell, H.: *Med. Klin.* 28: 150 (Jan. 29) 1932.
Biering, W. L.; Bone, H. C., and Lockhart, M. L.: Use of the Electro-stethograph for Recording Heart Sounds, *THE JOURNAL*, Feb. 23, 1935, p. 628.
Narat, J. K.: *Illinois M. J.* 70: 131 (Aug.) 1936; *Ztschr. f. Kreislauforsch.* 29: 313 (May 1) 1937.

As to the desirability of the amplification, graphic recording of sounds is impossible without it. In turn, the importance of sound registration has been stressed by many prominent cardiologists:

- Cabot, R. C.: A Multiple Electrical Stethoscope for Teaching Purposes, *THE JOURNAL*, July 28, 1923, p. 298.
Groedel, F. M.: *Verhandl. Deutsche Gesellsch. f. inn. Med.* 41: 372, 1929.
Wohlers, H., and Duchosal, P.: *Arch. méd. d. mal. du cœur* 25: 1, 1932.
Trendelenburg, F.: *Med. Klin.* 28: 146, 1932.
Sacks, H. A., and Marquis, Harold: *Proc. Soc. Exper. Biol. & Med.* 32: 773 (Feb.) 1935.

Lack of space prevents enumeration of the great array of reasons why a graphic recording of sounds is desirable. Only a few can be mentioned here.

The customary method of auscultation with a stethoscope is fraught with the danger of personal equation, as the auditory perception varies greatly in different individuals. The matter becomes still more complicated by the lack of uniformity in terminology. Records obtained from the same patient at certain intervals enable the physician to follow the evolution of the condition and the effect of therapeutic measures. Some amplifying and recording devices offer facilities for a simultaneous auscultation of heart sounds by more than one person, so that an immediate comment or interpretation is possible. Tracings of heart sounds offer ample opportunity for investigations of theoretically and practically important cardiologic problems.

Apparatus for amplification and registration of heart sounds have been simplified to such an extent that they can be used not only in scientific laboratories but also by practicing physicians. Not the apparatus, but it a common stethoscope or an amplifying device, but the auscultating physician makes the diagnosis.

JOSEPH K. NARAT, M.D., Chicago.

This letter was sent to Dr. Macfarlan, who replies:

To the Editor:—My article dealt primarily with the acoustic characteristics of stethoscopes used in general practice, and it brought out the fact that they do not amplify sound. The statement under criticism, "Amplification of heart and lung sounds is neither practical, nor desirable, nor needed for the physician with normal hearing," is challenged by your correspondent, who states that amplification is desirable as being (1) possible of graphic recording (2) or in showing fine differences (a) unaffected by the "danger of the personal equation" and (b) the complication of "lack of uniformity in terminology." Undoubtedly, acoustic analysis of heart and chest sounds will advance to a science, but it will have to pass through a long period of development similar to the study of hearing across the frequency range. The latter has been intensively considered by a small group of otologists for at least ten years and is not yet out of the fog. Any of these workers will agree that the findings vary enormously with the type of instrument used in the testing (see the article by Austin A. Hayden, "Hearing Aids from Otologists' Audiograms," *THE JOURNAL*, August 13, p. 592). Graphic recording by all human means is subject to wide variation and error, and the incapacities of audion circuits and phonograph recordings are fully as objectionable as the personal equation present when the trained examiner is listening to the heart or lungs either without an instrument or with the common stethoscope.

Until a time when electrical amplification is perfected, I would say that I would not modify the statement "amplification of heart and lung sounds is neither practical, nor desirable, nor needed for the physician with normal hearing."

Since the publication of the original article, I have had many letters from physicians who get their best information from the use of the unaided ear. A number of them decry the substitution of instruments for trained observation, and it is worth recalling that in the human ear itself we have a mechanism infinitely more delicate than any instrument, to determine variation in the character and quality of sound.

DOUGLAS MACFARLAN, M.D., Philadelphia.

INTENSIVE TREATMENT OF SYPHILIS

To the Editor:—In the Paris letters March 12 and June 25, published respectively in *THE JOURNAL* April 9 and July 23, appeared reports under the title "The Intensive Treatment of Syphilis." These reports emanated from Dr. Arnault Tzanch and Dr. Paul Chevallier. These authors are using massive doses of arsphenamine in the treatment of syphilis, using the drip method. One death is reported in their series. My purpose in this communication is to call attention to two points:

1. No mention is made by these authors of my prior work done in association with Dr. Louis Chargin and Dr. William Leifer (*The Application of the Intravenous Drip Method to Chemotherapy as Illustrated by Massive Doses of Arsphenamine in the Treatment of Early Syphilis*, *THE JOURNAL*, March 16, 1935, pp. 878-883). This is the more curious since in the official journal of the hospitals of Paris (*La semaine des Hôpitaux de Paris* in its issue of June 1, 1935, No. 11, pp. 328 to 335, under the title "Le goutte à goutte intraveineux en Amérique" by Dr. M. Ph. Dally) every bit of work I did on the intravenous drip has been abstracted, in most instances by literal translation, and on page 333 saying: "Le goutte à goutte a été essayé dans la syphilis, par Chargin et Leifer. Vingt-cinq hommes, en état

de syphilis primaire ou secondaire, recurrent pendant cinq jours en moyenne 4 gr. d'arséno-benzol, sans autre réaction qu'une fièvre quelquefois alarmante. Dans 95% des cas observés après cette stérilisation, le Wassermann resta négatif pendant trois mois, bien qu'aucune autre médication n'ait été employée. Mais ces essais, si encourageants qu'ils soient, sont encore à l'état expérimental."

2. More important is the fact that these workers are not following either the indications for treatment, the selection of patients or the technic which I described. Hence this work must not be confused with my work, which is in the process of more extensive confirmation and concerning which I shall publish a report at greater length at a later date when I have completed my plan of study.

HAROLD THOMAS HYMAN, M.D., New York.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ACUTE ALCOHOLISM AND ANESTHESIA

To the Editor:—If a person is so completely under the influence of liquor as to be unconscious, could or would an anesthetic be administered to the person before complete recovery from intoxication, before an operation could be performed? One of the members of my office staff asked me this question, but I could not give him an answer. M.D., Illinois.

ANSWER.—A person who has become unconscious from the influence of too much alcohol is not a safe candidate for inhalation anesthesia or for general anesthetics administered by the rectal or intravenous route. Any person in this condition from the effects of alcohol is in a state of toxemia and more than likely the blood pressure is low, the patient's skin is moist and pallid and general anesthesia by inhalation or other route would be a definite hazard. One could not predict what the effect of a general anesthetic agent would be on the patient's cardiac mechanism or on the higher cerebral centers but it would probably be unfavorable. Minor surgical procedures can be, and have been, done on persons unconscious from the effects of too much alcohol, and the judicious use of local anesthesia may be tried if it is necessary. If the operation to be performed on a patient unconscious from the influence of alcohol must be done under general anesthesia, it is best to wait until the patient has recovered from the effects of the alcoholic excess. If the operation on the patient in this condition is one which requires immediate attention, regional methods of anesthesia should be employed. The usual supportive measures (administration of stimulants and intravenous administration of fluids) should be used.

ARE FROGS POISONOUS TO EAT?

To the Editor:—I have three patients who had symptoms confined to the urinary tract with albumin and blood in the urine after eating green frogs. Are there any frogs which are poisonous to eat and do you think frogs are a factor in these cases? M.B., Canada.

ANSWER.—It is difficult to answer this inquiry because adequate information regarding the variety of frog eaten and the method of preparation is lacking.

The green or spring frog (*Rana clamitans*), which is commonly found in abundance in eastern North America from the Gulf of Mexico to Hudson Bay, is considered an edible variety. This frog is described by Wright (Frogs: Their Natural History and Utilization, U. S. Dept. of Commerce, Bureau of Fisheries, Document 888, 1920) as having two ridges down its back. "The forward upper parts are bright green; the posterior region brown or olive. The under parts are white, with some marbling; in the male the throat is yellow. This species reaches 3½ to 4 inches in length. . . ." It is understood, however, that several other varieties occurring in various parts of the United States are also commonly known as green frogs, and

that, in general, the green frog is not as widely used for food as the bullfrog or the spotted, or leopard, frog.

A search of the medical literature has revealed no reports of toxicity resulting from eating any variety of cooked frogs' legs. Opinions regarding the edibility of any particular variety appear to be based chiefly on size and relative abundance. Of course the possibility of spoilage or of contamination by the toxins of the skin of improperly dressed frogs should be considered. However, there appears to be no available evidence that any variety of frogs' legs is toxic when properly skinned and cooked.

ORAL IMMUNIZATION FOR TYPHOID

To the Editor:—What is the present status of oral immunization against typhoid? H. C. WIGER, M.D., Rice Lake, Wis.

ANSWER.—The work of Besredka was primarily responsible for initiating the use of oral typhoid vaccine. Essentially his claim was that, in addition to general immunity to bacteria, it is possible to produce immune bodies in the tissues locally. So far as the intestine is concerned, he felt that the preliminary treatment of bacteria with bile facilitates this mechanism.

Most of the statistical data presented in the various papers show evidence of difficulty in control. The papers deal principally with epidemics and are for the most part obviously poorly controlled. The laboratory work with animals, on the contrary, was usually satisfactory. However, even when agglutinins were obtained, it is obvious that the satisfactory production of these immune bodies in experimental animals is not necessarily conclusive evidence of the production of true immunity in man.

Judging from the available evidence, it would seem that oral vaccination should be eliminated entirely as a method of treatment. As a means of preventive immunization, however, it may be justifiable to use it in those instances in which the subcutaneous method is not practicable.

Pending more conclusive evidence for the value of oral typhoid vaccination, commercially available products have not been accepted by the Council on Pharmacy and Chemistry.

PLEURISY WITH EFFUSION AND SYPHILIS

To the Editor:—A Negro aged 25, having right pleurisy with effusion, gives no history of contact to tuberculosis. His Mantoux test is negative to tuberculin both 1:5,000 and 1:100. He had a chancre three years ago, for which he received treatment for only three months. His blood Wassermann reaction, as well as the complement fixation test for syphilis on the pleural fluid, is 4 plus. A roentgenogram taken after tapping is negative for parenchymal involvement of the contralateral lung as well as of the lung area above the fluid level. Could one positively exclude tuberculous infection, assuming that the technic of the Mantoux test is correct? Is one justified in making a diagnosis of syphilitic pleurisy with effusion, should such an entity exist? Is it possible for pleural fluid of a tuberculous pleurisy to give a positive complement fixation test for syphilis? M.D., New Jersey.

ANSWER.—It would be impossible absolutely to exclude tuberculosis on the basis of the negative tuberculin test. No biologic test is 100 per cent accurate and there is the occasional person with definite tuberculosis whose tissues apparently are not sensitized sufficiently to tuberculo-protein to react to the tuberculin test. Probably this group does not constitute more than 1 or 2 per cent of infected persons. A similar situation has been known since 1893 to exist among animals. In extensive disease of an acute nature which is overwhelming, either in patients who are nearing death with chronic disease or in patients with acute diseases such as meningitis, pneumonia and generalized miliary disease, the tissues become desensitized and thereafter fail to react to the tuberculin test. However, with no manifestation of clinical lesions except pleurisy with effusion such desensitization should not have occurred. It would be worth while to centrifuge some of the fluid and stain the sediment for tubercle bacilli. If they are not found, Corper's medium might be used to advantage for the growth of cultures or animals might be inoculated. In this manner tuberculosis can be reasonably well ruled out if no positive observations result.

It is possible that beneath the fluid level a lesion exists in the lung which might be due to any one of a number of infections. Complete removal of the fluid, followed by x-ray film examination, should determine this with a reasonable degree of accuracy. It is possible for a gumma to be present in the lung and associated with the pleural effusion. However, gumma of the lung apparently is a rare condition and difficult to diagnose accurately. Diagnosis is sometimes made wholly on the response to antisyphilitic treatment. Either gumma of

the lung or basal lobe tuberculosis would cast a shadow on the x-ray film after the fluid is removed if the lesion is macroscopic.

Pleurisy with effusion caused by *Spirochaeta pallida* per se apparently is an extremely rare condition; otherwise one would expect to find reports concerning it in medical literature. Therefore one would need more evidence than a four plus complement fixation test for syphilis on the pleural fluid, since fluid removed from any serous cavity of a syphilitic patient might show such a reaction even though the immediate cause of the accumulation of fluid was not syphilis.

ALLERGY FROM YELLOW JACKET STING

To the Editor:—A druggist aged 65 says he was stung by a hornet when 12 years old and was unconscious for an hour. He has had good health ever since except for an attack of pneumonia about eighteen years ago which terminated with empyema and rib resection. He has been robust since recovery. Two years ago he was stung by a yellow jacket and was unconscious for twenty minutes. A few days ago he was again stung by a yellow jacket. He was unconscious for more than two hours and has felt miserable ever since. He was alone when this occurred, and when he regained consciousness he could not speak for quite a while. A gummy-like perspiration stood out all over him and his clothing was saturated. I did not see him at either time so I cannot give definite data as to pulse or blood pressure. Please discuss this condition with reference to treatment. It took from ten to fifteen minutes each time after being stung before he became helpless. If he could carry something with him for a prophylactic he would have time to use it. Honey bees and bumblebees do not affect him in the same way.

A. J. FAWCETT, M.D., Glendale, Ore.

ANSWER:—The case described is unquestionably an instance of anaphylactic-like shock from sensitiveness to bee sting. A number of such cases have been reported. Most of the case reports mention the honey bee as the source of allergy. Many others do not specify the species of bee involved. It is not surprising that there should be such a high grade specificity in the patient so that he would be allergic to the hornet and yellow jacket and not to the honey bee or bumble bee. Among the first authentic cases on record are those of Waterhouse (*Lancet* 1:946, 1914) and Hubert (*Lyon méd.* 138:678, 1926). In experiments on bee sensitive individuals Benson and Semenor (*J. Allergy* 1:105 [Jan.] 1930) found that the allergy is not one of specificity to be venom but rather an allergy to the protein of the whole bee. There are several reports dealing with the effectiveness of specific desensitization of these bee sensitive individuals with an extract made from the bees. The following references will be worth while in that connection: Braun (*S. African M. Rec.* 23:408 [Sept. 26] 1925); Benson and Semenor (*J. Allergy* 1:105 [Jan.] 1934). One might consider such specific treatment in the case cited in the query. However, because of the infrequency of these attacks and because of lack of occupational exposure, such treatment would probably be impractical. The use of a hypodermic injection (0.5 cc. of 1:1,000) of epinephrine hydrochloride immediately after the bee sting might minimize the allergic reaction to a considerable extent.

PERNICIOUS ANEMIA AND DIARRHEA

To the Editor:—A married woman aged 59 was operated on for exophthalmic goiter in 1928 and had pernicious anemia in 1933. Since then she has taken two capsules of extralin three times a day, weekly intramuscular injections of concentrated liver extracts, reduced iron and twenty drops of diluted hydrochloric acid. Recently she had explosive watery stools, as frequent as six a day. The blood count on July 5 showed hemoglobin 84 per cent, erythrocytes 4,350,000, leukocytes 10,000, color index 0.9 plus with a differential count of neutrophils 46 per cent, eosinophils 3 per cent, small lymphocytes 43 per cent, large lymphocytes 4 per cent, metamyelocytes 4 per cent, erythrocytes normal. Can you suggest treatment to overcome watery stools? M.D., Pennsylvania.

ANSWER:—Whether the diarrhea in this case is related to the anemia or to the treatment the patient is receiving is not clear. The stools should be examined for such conditions as amebic dysentery and the possibility of carcinoma of the colon should be considered. The only possible explanations on the basis of the data given are that: 1. The diarrhea may be related to the iron. This is not likely, since the patient has taken iron for several years without symptoms. 2. The diarrhea may be on a vitamin deficiency basis. A deficiency in vitamin B is sometimes seen accompanying pernicious anemia. This can be remedied by giving an ounce of brewers' yeast three times daily or by using relatively unconcentrated liver extracts. Many of the newer ultraconcentrates do not contain the substance necessary to stop the diarrhea in vitamin B deficiencies. 3. The diarrhea may be related to the lack of acid in the stomach; in this case an increased dosage of hydrochloric acid might be given with advantage.

LONG CONTINUED ATTACKS OF EPIGASTRIC PAIN AND VOMITING

To the Editor:—An insurance agent, aged 52, married, had a mastoid operation at 25. When about 30 years old he began having attacks of epigastric pain accompanied by vomiting. An appendectomy failed to give relief. Ever since this time, at intervals of from a few weeks to six months, he has had attacks of epigastric pain of increasing severity. Profuse secretion of saliva precedes vomiting a half hour to an hour. The vomitus is at first stomach contents followed by the contents of the duodenum. The pain in the epigastrium is severe and during some of the attacks vomiting occurs every fifteen minutes and has lasted several days. Occasionally there is remission of two days with recurrence of the pain and vomiting. The patient is well nourished and if free from attacks for several months gains weight rapidly. The heart and lungs are normal and the head and neck are normal aside from the scar from the mastoidectomy. There is no abdominal tenderness except during an attack, when it is confined to an area 5 cm. in diameter slightly to the right of the midline and just below the costal margin. The urine is normal and the Wassermann reaction negative. The basal metabolic rate is from minus 24 to minus 16. X-ray examination of the gastrointestinal tract and the gall bladder (dye administered) is negative. Chemical examination of the stomach contents shows no free or combined hydrochloric acid. Blood counts are normal. The blood chemistry is negative. The patient has received thyroid, diluted hydrochloric acid and phenobarbital without relief. Any information you can offer regarding diagnosis or treatment will be appreciated.

M.D., California.

ANSWER:—The occurrence of epigastric pain and vomiting over a period of twenty-two years without physical deterioration argues against serious organic disease. A food sensitization should be ruled out. Sea foods, certain nuts and fruits are notorious offenders and many other foods have been implicated. Has any relationship between the ingestion of certain foods and the attacks been noted? Patch tests might be helpful.

Salivation for a considerable period before the vomiting suggests the possibility of a diaphragmatic hernia or an esophageal diverticulum. Both of these conditions may produce reflex pylorospasm and vomiting. A small hernia through the esophageal opening might easily escape detection. Such a hernia is best demonstrated by examining fluoroscopically following the ingestion of barium sulfate and with the patient in the Trendelenburg position. The intermittence of the attacks would be based on the assumption that the abdominal contents did not constantly protrude through the esophageal orifice. The less likely esophageal diverticulum should be sought for by fluoroscopy at various angles. Osteoarthritis of the spine has been known to produce spasm of the gastrointestinal tract through irritation of the sympathetic nerves. This possibility seems unlikely in this instance, but is worth consideration.

The other common causes of vomiting in the absence of gastrointestinal disease seem fairly well ruled out either by the examination or by the time the condition has persisted. Among these causes are gallbladder and kidney stone, movable kidney, intestinal parasites, brain tumor, myelitis, tabes and various intoxications.

The achlorhydria requires further consideration. If the achlorhydria is complete and continuous, one must consider the various causes of this condition. In view of the relatively good health between the attacks, it seems unlikely that a continuous achlorhydria exists. Before it is assumed that such is the case, the secretory apparatus should be stimulated with alcohol or with histamine.

Lastly, nervous vomiting must be considered. There is no doubt that in an individual with a certain neurogenic background emotional stress will produce such a picture as is described. The anacidity might be explained on a similar basis. It should be remembered that this diagnosis should not be made until all organic causes have been ruled out.

Intelligent suggestions for treatment cannot be made until a satisfactory diagnosis is achieved.

TESTS FOR SPIROCHETAL JAUNDICE

To the Editor:—How should one prepare a specimen of blood for dark-field examination for *Leptospira icterohaemorrhagiae* of Weil's disease? These organisms are found in the blood during the first week or before the onset of icterus.

SAMUEL IRGANG, M.D., New York.

ANSWER:—Considerable difference of opinion exists concerning the reliability and the technic of diagnosing Weil's disease by the darkfield demonstration of spirochetes (*Leptospira icterohaemorrhagiae*) in human blood. There is no generally accepted method of performing this test. Best results are secured during the first five days of the disease.

The following methods can be tried: 1. Examine fresh citrated whole blood directly. 2. Centrifuge fresh citrated blood at a speed just sufficient to precipitate the blood cells and examine a thick layer of the supernatant plasma. It has been shown that high speeds are necessary to precipitate the spirochetes. 3. Separate the blood cells by the aforementioned method.

Centrifuge the plasma at high speed (3,500 revolutions per minute) for several minutes, remove a portion of the supernatant plasma and repeat several times. In this manner it may be possible to concentrate the spirochetes from the original volume of blood into a cubic centimeter of plasma, thus rendering their detection easier.

A positive test confirms the diagnosis of Weil's disease. A negative test proves nothing, since many investigators have failed to demonstrate spirochetes by this method in proved cases of Weil's disease.

Beginning about the tenth day and increasing until the twentieth day, spirochetes appear in the urine and may occasionally be demonstrated by darkfield examination of the sediment from 50 cc. of freshly voided urine.

Weil's disease presents such a variable clinical picture that laboratory procedures should confirm or reject every clinical suspicion of its presence. Unfortunately many laboratories are not equipped for this type of work. If the darkfield examination proves unsuccessful, other tests should be tried. These include (1) inoculation of blood or urine into guinea pigs, (2) culture of the patient's blood, (3) agglutination procedures (positive in increasing titer after the sixth to eighth day of the disease), (4) the complement fixation test, (5) the precipitation test and (6) the adhesion test.

The following papers review the present status of Weil's disease in the United States and contain references to the extensive literature:

Gaines, A. R., and Johnson, R. P.: Weil's Disease, *Arch. Int. Med.* 60: 817 (Nov.) 1937.

Jeghers, H. J.; Houghton, J. D., and Foley, J. A.: Weil's Disease, *Arch. Path.* 20: 447 (Sept.) 1935.

LICE FROM SWIMMING POOL

To the Editor:—Please inform me whether one would be likely to pick up head lice in a swimming pool. The theory advanced is that head lice will leave the human head when submerged in water. There has been an epidemic of head lice among children using a local pool.

M.D., New Jersey.

ANSWER:—Yes, a swimming pool might be a good source of pediculosis capitis among children, whether the lice swim or stay on the head, for children in play handle each others' heads and swap caps. No child with head lice should be admitted to a swimming pool or any other playground.

"CREOSOTE OIL" IN CONJUNCTIVA

To the Editor:—In the process of creosoting lumber, the creosote oil often gets into the eyes of the workers. This seems to be quite painful but does not result in serious injury. An oily solution seems to be the best thing to use, as creosote will not mix with water. What is the correct treatment?

M.D., Michigan.

ANSWER:—"Creosote oil" is the name generally applied to the fraction of the coal tar distillate which boils between 200 and 300 C. According to the specifications pertaining to the physical characteristics is a clause that "creosote oil" must contain from 8 to 10 per cent of the phenols as shown by extraction with sodium hydroxide solution. Among other substances in this greenish yellow fluorescent liquid are naphthalene, anthracene, pyridine, quinoline and acridine. Some of these are water soluble while others are not, but all are irritating to the conjunctiva. Consequently it is impossible to say which of the constituents in "creosote oil" cause the conjunctival irritation and which solvent is proper. But as in the case of any other irritating chemical substance that enters the conjunctival sac, mechanical flushing is of greater value than the use of a solvent which in itself may be irritating.

PRESCRIPTION WRITING

To the Editor:—For years I have been using the British method for prescribing solutions; e. g., dilaudid, gr. 1/64; ammonii chloridi, gr. ii; syrupi cerasi ad 5i; M mitte doses, No. xxxii Sig 5i every 3 hours for cough. I have been criticized by a pharmacist for using this method. If it is right to use this method for pills, capsules and powders, why not for liquids?

M.D., Massachusetts.

ANSWER:—Writing for single doses in prescriptions, whether for liquid or solid medication form, is decidedly objectionable if for no other reason than that the necessary multiplication must be carried out by the pharmacist, who might have no one to check him in case he makes a mistake. When the physician does his full duty by the prescription and writes it in its finished form, including the necessary multiplication, two checks are exerted on a possible mistake in calculation: by the physician in his "proof reading" of the prescription and by the pharmacist who will, if he has any doubt, actually divide the total quantity

by the prescribed number of doses to make sure that no mistake has been made. If the patient dies in consequence of a mistake, the misfortune is just as great whether it is the doctor's or the druggist's fault, and it is less likely to happen if both bear the responsibilities as they should. Medical teachers sometimes call the simple dose method of prescribing the "lazy doctor's document."

HARDENING SKIN OF HANDS?

To the Editor:—The girls working in an industry in Easton are subject to numerous blisters and defoliation of the skin as a result of taping coils with a plain untreated cotton tape. This tape is wrapped about the coil, each turn of the tape overlapping the preceding turn. The girls pull firmly on the tape at each turn, and the subsequent friction causes the blistering and lacerations. Could you suggest any hardening or toughening solution for the fingers? It is my understanding that pugilists use a strong briny solution for this purpose.

JOHN HOWELL WEST, M.D., Easton, Pa.

ANSWER:—It is true that prize fighters soak their fists in brine to toughen them. Whether this is a practical solution of the problem is not at all certain. Experiment is necessary to decide. Care must be taken that the brine salt is not allowed to crystallize on the skin, for salt crystals are definitely harmful. Fish picklers, those who prepare gut for violin strings and other purposes and those who pack ice cream in rock salt and ice have chronic ulcers, called "salt holes," and various infections of the skin. Rinsing with water and the use of fats on the skin protect against this harmful action.

UNEQUALLY DEVELOPED BREASTS AND MENSTRUAL IRREGULARITY IN GIRL

To the Editor:—A girl aged 15 complains of menstrual irregularity and of unequal development of the breasts. She is 63 inches (160 cm.) tall, weighs 132 pounds (60 Kg.) and has a blood pressure of 128 systolic, 80 diastolic and a heart rate of 72. She has been menstruating for two and one-half years, her periods being from five to six weeks apart. The flow is moderate, lasting from four to five days; she has no cramps and doesn't pass any clots. She is well developed and has a fair growth of hair on the upper lip. The thyroid gland is not enlarged. The chest is symmetrical. The right breast is rather large, with a moderately well developed areola. The nipple is inverted. The left breast is about a fourth the size of the right and has the appearance of an 11 or 12 year old girl's breast. The nipple is not well developed and is inverted. There is some tendency toward a panniculus adiposus in the lower part of the abdomen. The pubic hair and external genitalia are normal. Rectal examination shows a retroverted uterus of normal size for the patient's age. The parents of the patient are both of small stature. An older sister is only 4 feet 11 inches (150 cm.) tall and has a low basal metabolic rate and some menstrual irregularity. A younger brother is below normal in weight and height for his age, although x-ray examination of the wrist bones shows normal development for his age. He is mentally alert but his mother states that he is slow in coming to in the morning and also slow in performing given tasks. Further inquiries in the family history elicited the fact that the patient has a cousin with unequally developed breasts. What course should be followed to equalize the breasts? What suggestions can be given for the correction of the menstrual irregularity?

M.D., Missouri.

ANSWER:—There is no safe way to attempt to equalize the patient's breasts except by surgical means and this is surely not advisable. If one breast were of huge proportions, a surgical operation might be justified but not otherwise. There is likewise no need to attempt to correct the patient's menstrual irregularity because it will do no harm to leave it as it is. Even if the prolonged menstrual interval persists for a year, there is still no reason to attempt to change it.

TORTICOLLIS IN INFANT

To the Editor:—A girl, 1 month old, delivered with low forceps, is found to have a rigid sternocleidomastoid with slight torticollis. What is your opinion as to the best time to operate and the best operative and postoperative procedures? The baby now weighs 8 pounds (3.6 Kg.); her birth weight was 7 pounds (3.2 Kg.). She now gets only bottle feedings.

M.D., Illinois.

ANSWER:—Torticollis due to hemorrhage within the sternocleidomastoid muscle is treated in the infant by gentle passive stretching of the head into an overcorrected position, to be done several times daily. This will frequently prevent permanent contracture and deformity. If the hemorrhage has extensively destroyed the muscle fibers and fibrosis occurs, it may later be necessary to sever the shortened fibrous bands. Usually this procedure can be delayed until after the first year. When surgical treatment is necessary it is best done by exposure of the sternal and clavicular ends of the fibrosed muscle, all contracted fibrous bands being severed. Postoperatively a plaster dressing which holds the head in an overcorrected position is used for a period of from three to six weeks. Passive and active stretching should be continued until there is no tendency for recurrence of the contracture.

EPIDEMIC DIARRHEA OF NEWBORN

To the Editor:—Last week I referred a case of infant feeding to a pediatrician in Omaha who stated that the epidemic of infant deaths in a Chicago hospital last fall, given so much attention in the newspapers, was due to Karo syrup. Was there any such report filed or made in the final summary by the people who had those deaths under investigation? At the University Hospital at Iowa City Karo syrup has been used extensively in the past, but I have had no occasion to ask about it lately. It was rather a jolt to me to hear this, and being ignorant about the matter I turn to you for advice.

J. CLARK COOPER, M.D., Villisca, Iowa.

ANSWER.—In the recent epidemic of diarrhea in the newborn, which occurred in a Chicago hospital, careful investigations failed to reveal the exact cause.

There was no evidence obtained that the condition was due to the use of any specific type of food, either carbohydrate or milk itself. Although several types of organisms were isolated from the stools and at necropsy, none of these were proved causative.

Several of the infants who suffered from the disease were completely breast fed. Others, while artificially fed, did not receive Karo syrup. Several types of sugar were employed.

A careful search of the literature has failed to reveal any outbreaks of epidemic diarrhea due to the syrup mentioned.

EVIPAL SODIUM RECTALLY

To the Editor:—Referring to Dr. Alfred E. Jones's article on Basal Anesthesia: The Use of Evipal by Rectum in THE JOURNAL April 30, I should like to ask the following question: If evipal sodium is destroyed by the liver, why is a 3 Gm. dose by rectum, which is absorbed by the portal circulation, not more dangerous than 1 Gm. by vein, which has to go through the systemic circulation before reaching the liver?

D. W. MATTHAEI, M.D., Fessenden, N. D.

ANSWER.—If 3 Gm. of evipal sodium is placed in the portal circulation at one time, as by direct injection into one of the hemorrhoidal veins, it would certainly be more dangerous than 1 Gm. injected into the cubital vein. Since 3 Gm. by rectum is even less toxic than 1 Gm. intravenously, the answer is that the drug is absorbed more slowly and therefore reaches the liver more slowly by the rectal route than when administered intravenously.

POSSIBLE HARM FROM SODIUM BICARBONATE

To the Editor:—Sodium bicarbonate will tarnish metal. How many grains may be taken on an empty stomach without injury?

M.D., New Jersey.

ANSWER.—Sodium bicarbonate is, on the whole, quite a harmless substance even when taken on an empty stomach. It is indeed taken with benefit by many sufferers from gastric catarrh and the usual dose in such cases is 1 Gm. (15 grains) in a cup of water as hot as one can drink it. Much larger doses are used in acidosis. When taken in teaspoonful doses and before each meal by a patient there is a possibility that the effect of the alkali on the system may lead to alkalosis.

INTRASPINAL THIAMIN CHLORIDE

To the Editor:—In Queries and Minor Notes (THE JOURNAL, May 28) mention is made of the danger of intraspinal injection of thiamin chloride. In my preliminary report entitled "The Intraspinal (Subarachnoid) Injection of Vitamin B₁ for the Relief of Intractable Pain and for Inflammatory and Degenerative Diseases of the Central Nervous System," which appeared in the *American Journal of Surgery* 39:495 [March] 1938), emphasis was laid on the possibility of vitamin B₁ poisoning from overdosage and the possible harmful effects of using thiamin chloride not especially prepared for intraspinal injection. It might be well to emphasize again the precautions mentioned in this article. It might be helpful to call attention to my article on this subject for the details of the rationale and plan of treatment in cases of multiple sclerosis. To date I have given 201 intraspinal injections of vitamin B₁ without a single fatality.

ELIAS L. STERN, M.D., New York.

NICOTINE IN CIGARETS—A CORRECTION

In Queries and Minor Notes, August 6, page 560, under the title "Nicotine in Cigarets" it is stated: "If one cigaret fell into a bottle of milk, the amount of nicotine extracted would hardly exceed 2 mg." This should have read: "If one cigaret fell into a bottle of milk, the amount of nicotine extracted would approximate 20 mg. This amount of nicotine, as well as some of the other extractives which would go into solution in the milk, would result in nausea before any toxic effects would develop and therefore the effect would probably not be particularly harmful."

Nevada May Examination

Dr. John E. Worden, secretary, Nevada State Board of Medical Examiners, reports the written examination held at Carson City, May 2, 1938. The examination covered eleven subjects and included ninety-nine questions. An average of 75 per cent was required to pass. Three candidates were examined, all of whom passed. Two physicians were licensed by reciprocity after an oral examination. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Southern California School of Medicine	(1938)	85.6
Long Island College of Medicine	(1934)	84.4
Medical College of the State of South Carolina	(1930)	80.9
School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Cornell University Medical College	(1921)	New York
University of Pennsylvania School of Medicine	(1927)	S. Dakota

North Carolina June Examination

Dr. B. J. Lawrence, former secretary, North Carolina State Board of Medical Examiners, reports the written examination held at Raleigh, June 13, 1938. The examination covered seven subjects. Eighty-five candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
College of Medical Evangelists	(1938)	1
Yale University School of Medicine	(1928)	1
George Washington University School of Medicine	(1938)	1
Georgetown University School of Medicine	(1933), (1938, 2)	3
Howard Univ. College of Medicine	(1935), (1937), (1938, 2)	4
Emory University School of Medicine	(1936), (1938, 7)	8
University of Georgia School of Medicine	(1938)	1
Northwestern University Medical School	(1937)	1
Rush Medical College	(1938)	1
University of Louisville School of Medicine	(1937), (1938, 2)	3
Johns Hopkins University School of Medicine	(1934), (1938, 2)	3
University of Maryland School of Medicine and College of Physicians and Surgeons	(1938)	1
Washington University School of Medicine	(1937)	1
Cornell University Medical College	(1938)	1
New York University College of Medicine	(1938, 3)	3
University of Rochester School of Medicine	(1930)	1
Duke University School of Medicine	(1937, 3), (1938)	4
Jefferson Medical College of Philadelphia	(1936), (1938, 8)	9
Temple University School of Medicine	(1938, 8)	8
University of Pennsylvania School of Medicine	(1938, 9)	9
Woman's Medical College of Pennsylvania	(1938, 2)	2
Medical College of the State of South Carolina	(1938, 4)	4
Vanderbilt University School of Medicine	(1931), (1938, 2)	3
Medical College of Virginia	(1938, 10)	10
McGill University Faculty of Medicine	(1937), (1938)	2

Fifty-two physicians were licensed by endorsement at the meetings held May 2, June 13 and July 28. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Columbian University Medical Department, D. C.	(1899)	Dist. Colum.

Book Notices

Handbook of Hematology. Edited by Hal Downey, University of Minnesota Medical School, Minneapolis. In four volumes. Cloth. Price, \$85 per set. Pp. 698; 699-1585; 1587-2360; 2362-3136, with 1,448 illustrations, including 50 colored plates. New York: Paul B. Hoeber, Inc., 1938.

The most monumental contribution on hematology assembled in English or in any other language has been made available by Hal Downey with the aid of an inspired publisher—the late Paul B. Hoeber. The position of hematology in modern medical practice is obviously paramount. The blood is the most important of all the tissues in the human body and is the very center of importance in relation to all manifestations of health and of disease.

In the development of the volumes, almost forty collaborators have participated. They have been given carte blanche as to the space to be occupied and as to their opinions and theories. The handbook constitutes a digest of international literature supplemented by an extensive bibliography and is in every sense an epoch-making contribution in the field of medical literature. The four volumes discuss every phase of the anatomy, physiology and pathology of the blood as well as that of the associated tissues, such as the bone marrow and the spleen, which are concerned in blood formation and blood destruction. Each of the important and well classified diseases of the blood is given special consideration and the other sections are devoted to the effects on the blood of diseases which are not primarily diseases of the blood and the blood-forming organs. There are hundreds of illustrations both in black and white and in colors.

The first section, by Raphael Isaacs, is concerned with the development, morphology, number, composition, measurement, and physical and chemical properties of the red blood cells. The second section gives a similar consideration to the leukocytes. The third section takes up the eosinophils. The fourth section considers the mast cells; the fifth section, the lymphocytes and monocytes. Then comes a consideration by Bunting of the functions of the leukocytes and a study of the blood platelets by Rosenthal, who also considered the hemorrhagic diatheses. The remainder of this volume is devoted to the supravital staining methods.

The second volume opens with a magnificent study of comparative hematology by H. E. Jordan and embryology by William Bloom. Next comes a consideration of the normal blood in infants and children and of the reticulo-endothelial system. This chapter, by the late Robert H. Jaffé, may also be listed among the classics in American medicine. Few hematologists have attained the distinction attained by Jaffé not only for fundamental knowledge but also for the ability to present information in a systematic, understandable form. The section on the reticulo-endothelial system would be well worthy of reprint as a special monograph. Dr. Downey himself discusses monocytic leukemia. Much of the remainder of the second volume is contributed by William Bloom, who discusses tissue cultures of the blood, the lymphatic tissues and the lymphatic organs. This section is supplemented by some of the finest colored illustrations that have been made available in any work on hematology.

The third volume is devoted largely to the spleen and the bone marrow, to changes that take place in these tissues, and to a consideration of the various anemias. The writers include Florence Sabin, Charles Doan, Cyrus Sturgis and Verne Mason among others. Here also the considerations and the illustrations are of the highest order.

The fourth volume is devoted to polycythemia, hemoglobin, metabolism, infectious diseases, sarcomas of the blood and many other subjects, and also provides an extensive detailed index.

The entire series of books is printed on a fine quality of enameled paper suitable to the quality of the illustrations. Obviously here is fundamental material which should be in the possession of every medical library and every medical school because it is the very foundation on which a great new specialty in medicine is developing. The editor, publisher and collaborators in this great new medical work deserve the commendation of the medical profession.

Die Methoden der experimentellen Chemotherapie. Von Prof. Dr. Claus Schilling, Abteilungsleiter am Institut Robert Koch I. R. Paper. Price, 4.50 marks. Pp. 104, with 18 illustrations. Jena: Gustav Fischer, 1938.

This is a practical manual of selected methods such as might be used in organizing a chemotherapeutic institute or in a course on chemotherapeutic experiments on animals. Methods of the greatest importance in producing infections are given in detail, those little used being merely referred to; choice of chemical compounds is limited to the well tried and tested, derivatives being dealt with briefly.

The supreme law of chemotherapy, according to the author, is that the drug must not injure the host. For this reason, every therapeutic experiment must be preceded by a pharmacologic experiment which determines the minimum fatal dose and the highest tolerated dose of a drug. The aim of chemotherapy is to destroy the parasites in the host or at least to injure them so that they may be rendered harmless by the natural processes of the host. He warns that few infectious diseases in man run the same course in animals. But chemotherapeutic agents are not to be used on sick human beings until they are extensively tested on animals. Similar, though not identical, infections in animals may serve as models, experimental leprosy for instance, and yield important information.

The distribution and localization of infections must be considered by the chemotherapist. Although chemotherapeutic action is generally intended to be direct on the parasite, many beneficial effects are produced indirectly. Therefore the complete chemotherapeutic trial includes tests on the parasite *in vitro* and *in vivo*. The solvent or medium in which a chemotherapeutic agent is dissolved or suspended is important for the success of a test; for instance, viruses and bacteria are not injured in warm physiologic solution of sodium chloride but spirochetes and protozoa are decidedly. For the host, the medium must be indifferent. It is material to chemotherapeutic action whether the agent is injected in a true or colloid solution or is itself a crystalloid or colloid. With all such details attended to, it would seem that the chemotherapeutic experiments outlined in this book should succeed every time.

The following experimental infections with chemotherapeutic treatment are presented in the first nine chapters: bacteria, spirochetes, protozoa, helminths, rickettsia, bartonella, viruses and tumors. The last three chapters present experiments on chemotherapeutic agents, i. e. theories of action, special actions and detection in body fluids of certain agents (mercury, germanin, atabrine, arsenic, atoxyl, gold, quinine and plasmochin). The illustrations consist of simple line drawings and are used to clarify characteristic features of a piece of equipment, an organismal cycle, a pose of a mosquito or an anatomic lesion. Structural formulas and doses for different species of chemotherapeutic agents are given throughout, and at the end of the book there are separate indexes of literature and of subject matter. Altogether this is a most practical and handy book for all medical research institutes and laboratories of pharmacology, pathology and bacteriology.

Civilization and Disease. By C. P. Donnison, M.D., M.R.C.P. With an Introduction by Sir Walter Langdon-Brown, M.A., M.D., Hon. D.Sc. Cloth. Price, \$3. Pp. 222. Baltimore: William Wood & Company, 1938.

Psychoanalysis has been a stimulus to the medical investigator to compare the behavior, habits, practices and diseases of the primitive tribes in various parts of the world with the same traits and customs in the form in which they are exhibited in civilized life, from the jumping off point of analysis of mental mechanisms producing the neuroses. Since Margaret Mead and Malinowski have made studies of South Sea Island tribes with particular reference to their sexual behavior, which in turn is considered significant in giving rise to neurotic conditions, the subject is not new. The present writer has gone further. To a medical officer from primitive backwaters, the fact was stressed on his return to England that the diseases which he had observed among natives were dissimilar to those which were common in Britain. Carefully making an analysis of the proportion of various types of conditions observed under civilized modes of living and those seen in various primitive environments, he produced the present interesting and rather stimulating book. He is handicapped in comparing the diseases

observed in civilization and outside it by the fact that many diseases diagnosed in natives have an atypical form. Then too it is difficult to get the cooperation of primitive persons to permit a careful examination and this, it appears, is particularly true with regard to neurosis and psychosis. Nevertheless it seems to have been possible to make a tentative study which is of some value. The author himself admits that figures, particularly those in the noncivilized group, are not forthcoming which will bear a comparison with the carefully kept statistics of Europe. Nevertheless there are some conditions which are almost never found among primitive people, for instance exophthalmic goiter. The author does point out that carcinoma is possibly more rare among the primitive people because of the fact that owing to other causes they seldom reach the age of susceptibility. Donnison goes into some discussion of particular diseases which are less frequent among primitive people and points out their etiologic background. He emphasizes a number of traits which are not particularly of cultural origin or necessarily due to civilization *per se*. On the other hand, dietary habits plus the strain of life under civilized conditions do, it appears to him, form an etiologic background for the higher incidence among the civilized of certain disorders. There is a good deal of discussion of the philosophic background of the anthropologic, ethnologic and perhaps the sociologic mechanisms which cause a difference between civilized and noncivilized groups. It will probably be the source of stimulation for other serious students of public health and for psychiatrists to make more valid comparisons. The volume is not particularly deep, nor does it show great conversance with either psychiatry or sociology. There are some parts which are redundant and somewhat out of place and this is particularly true of the author's rather extensive discussion of the various theories of neurosis. It must be admitted, however, that the book is well written and is interesting. While much of it may be considered controversial, it has a definite place in evaluating that borderline which lies between medicine and ethnology.

Progressive Relaxation: A Physiological and Clinical Investigation of Muscular States and Their Significance in Psychology and Medical Practice. By Edmund Jacobson, A.M., Ph.D., M.D., Laboratory for Clinical Physiology, Chicago. Second edition. Cloth. Price, \$5. Pp. 494, with 89 illustrations. Chicago: University of Chicago Press, 1938.

In 1929, when the first edition of this book appeared, the potential value of the special relaxing procedure was recognized in the pages of *THE JOURNAL*. Jacobson's method of treating the emotionally maladjusted has now become fairly generally known among psychiatrists and neurologists even if it does not have quite the recognition that some of the other forms of psychotherapy have. Strictly speaking, perhaps, Jacobson's method of progressive relaxation is not a psychotherapeutic method but rather a technic of treatment which attempts to get at disease states through adjustment of the individual's neuromuscular mechanisms rather than his thinking processes. After considerable research in the field of physiology and a good deal of reading on the subject of relaxation and neuromuscular mechanisms, in 1929 Jacobson came out with this theory, which at that time was quite novel; namely, that with complete relaxation came the opportunity for the individual with disturbed kinetic function to reach an equilibrium, at least a state of rest, which would permit nature to aid him in returning to a healthy state. Jacobson emphasizes the distinction which he draws between the advice that is usually given to the patient "to relax" and the systematic procedure of guidance which enables the patient to learn for himself through subjective sensation what real relaxation is, contrasted to what the patient thinks is a state of rest, which really contains a number of active components. Jacobson makes no attempt to limit this treatment to the anxiety neuroses and those conditions which frankly are accompanied by what might be called nervous tension. As a matter of fact, he gives some statistics in the present volume which indicate that cardiovascular states and other similar disturbances of the organism which are considered definitely organic in nature can be improved by this method. The first part of the book is devoted primarily to the scientific thought behind the method, and the experiments which have been done by the author and

other students of the subject indicate that progressive relaxation might be a therapeutic medium. Accompanying this considerable space is devoted to actual procedure of administering progressive relaxation. Although the author admits that the procedure is time consuming, it does not compare (when one analyzes the amount of time that must be given to teaching the patient how to relax properly) to the conventional psychotherapeutic measures, some of which go on interminably. The middle of the book—and this part constitutes about half of its total content—is devoted to an analysis of the physiologic components of progressive relaxation. The effect of relaxation on the knee jerk, for instance, is discussed in considerable detail. In the present edition the author has added a great deal of material dealing with the measurement of relaxation and tension of muscles by means of electrical measuring devices. The detail into which he goes here is almost overwhelming. The whole procedure of relaxation becomes almost a quantitative study. The terminal chapters deal with the use of this technic with particular reference to various disorders, traumatic and psychogenic. There is some indication of the fact that in the period of almost ten years during which the author has been following this procedure it has proved itself to have considerable value in his hands. Its use by others than the author has not been particularly convincing. Nevertheless it is a procedure which should be carefully studied and analyzed and tried by the neurologist and psychiatrist, and perhaps by the self-critical physician who is aware of neuromuscular disturbances in the organic state. There is an excellent bibliography. The style is good. The book is well written and, while the reasoning may not entirely be agreed with, the presentation shows a distinct effort to emphasize the truly scientific side of the author's work on the subject.

Tissue Reactions in Bone and Dentine: A Morpho-Biological Study of the Formation and the Dissolving of Bone and Dentine. By Ake Wilton, M.D., Asst. Professor and Lecturer in Pathology at the Caroline Institute, Stockholm. Paper. Price, 15s. Pp. 194, with 64 illustrations. London: Henry Kimpton, 1937.

This monograph is devoted to the exposition of the hypothesis that bone and dentin changes in such diseases as rickets, achondroplasia, scurvy, experimental hyperparathyroidism, Paget's disease and osteogenesis imperfecta are markedly influenced by two factors. One of these operates on rapidly growing normal tissues particularly during the developmental stage, when proliferation is greatest, tending to arrest growth and retard orderly development (differentiation) of embryonic types of cells from youthful forms to mature ones. The other acts on fully grown, working cells in which proliferation has ceased causing a dedifferentiation of them to less mature forms (metaplasia) and followed by proliferation. It is asserted that the changes in rickets and achondroplasia are typical of the first type of change, osteogenesis imperfecta and scurvy of the second. It is apparent that the author's point of view has been greatly influenced by the work of Häggqvist and his theory of bone calcification and decalcification. The exposition is not clear enough to satisfy the needs of a person unfamiliar with research in this field, and the content hardly justifies careful study by those familiar with current investigation of the problems discussed. The translation is not wholly satisfactory.

The Relationship Between Characteristics of Personality and Physique in Adolescents. By P. S. de Q. Cabot, the Psychological Laboratory, Harvard University, Cambridge, Massachusetts. Genetic Psychology Monographs, 1938, Vol. XX, No. 1. Paper. Pp. 120, with 3 illustrations. Provincetown, Massachusetts: Journal Press, 1938.

The author of this little monograph points out that since the time of Hippocrates there has been a series of attempts made to point out differences in personality in relation to actual physical structure. The purpose of the present study was to see whether any particular psychologic traits were associated with specific body build. The monograph begins with a summary of the literature on the subject, and the author draws the conclusion that the information is incomplete and the statistics are poorly collected, and he comes to the conclusion that most of the observers have found relationship of mind capacity to body structure but that their conclusions are drawn from insufficient data. The study reported in the present monograph comprised sixty-two cases classified as pykno-somes,

leptosomes and athletosomes. The cases were rated by at least four teachers for each student. A classification sheet was made listing the various traits emphasized by Kretschmer, a list comprising thirty-nine questions was used to analyze each case, and a trait study was made. Other information such as physical condition and intelligence quotient was also collected. The author formulates a hypothesis of sociobiologic advantage to determine whether any particular physical build was superior to another. In general the pyknic type were found to have the most satisfactory traits for a social adjustment. This is a carefully worked out study containing thirty-six tables, the data which are contained therein being treated by psychologic statistical methods, with the drawing of fairly valid conclusions. It is an interesting study from the standpoint of emphasizing the need for caution in using body-build types to represent mental types, although there probably is some relationship.

Arthritis, Fibrositis and Gout: A Handbook for the General Practitioner. By Charles W. Buckley, M.D., F.R.C.P., Physician to the Devonshire Royal Hospital for Rheumatic Diseases, Buxton. Cloth. Price, 7s. 6d. Pp. 153, with 24 illustrations. London: H. K. Lewis & Co., Ltd., 1938.

The author of this little book has collected and revised a group of postgraduate lectures aimed to give the essential clinical features of those disorders commonly grouped together as chronic rheumatism and to outline methods of treatment which he has found useful. The result is a book of seventeen chapters in which are discussed briefly the classification, theories of etiology, clinical features and treatment of rheumatoid arthritis, chronic villous arthritis, osteo-arthritis, spondylitis, fibrositis and gout. The author makes no claim toward thoroughness of discussion and cites the literature only occasionally. A short bibliography, however, is given at the end. Many useful hints for treatment are included and some suggestions are made which have not yet been generally accepted.

Neuro-Ophthalmology. By R. Lindsay Rea, B.Sc., M.D., M.Ch., Ophthalmic Surgeon to West End Hospital for Nervous Diseases, London. Cloth. Price, \$9. Pp. 568, with 161 illustrations. St. Louis: C. V. Mosby Company, 1938.

As the author points out, there is developing a close relationship between ophthalmology and neurology. Conditions revealed by examination of the nerves supplying the eye often are extremely significant in making a diagnosis of systemic disease or localized disease of the central nervous system. Since the appearance many years ago of "The Eye and Nervous System" by Posey and Spiller, no volume has specifically presented the facts needed by the neurologist so that he might more fully understand ophthalmic symptoms. It has been necessary for him to wade through textbooks on ophthalmology to find symptoms related to nervous system disease, yet even here discussions were sketchy as were those on the same subject in a neurologic book. Rea has to some extent overcome this problem. The whole of the volume is devoted to an analysis of diseases of the nervous system as manifested by ocular and extra-ocular symptoms pertaining to the visual mechanism. Discussions of neurologic symptoms manifested through the eye are relatively complete, but the parts of the book devoted to the influence of certain diseases of the nervous system on the eye are not quite as satisfactory. It is true that in his introduction the author expresses a desire to limit the size of this volume and perhaps it is justifiable to contract individual discussions of the ophthalmic conditions found in various nervous diseases, or as a result of various types of poisoning, on the basis that a thorough study of the chapters dealing with the symptoms found in the retina or in the extrinsic muscles of the eye will reveal what nervous diseases should accompany them. There is no particular novelty about the illustrations, but there are several color plates which show fundus conditions and there are a number of drawings giving perimetric results or showing pathologic conditions of one sort or another. Neuropathology is not stressed, nor is the branch of neuro-ophthalmology which is so important in this country, the medicolegal aspect of blindness, particularly that due to industrial conditions or to malingering, given any particular thought. The fact that neuro-ophthalmic symptoms and diseases having neuro-ophthalmic symptoms are discussed in one volume without particular classification makes the book a little

bit unsystematic. Some chapters are devoted to symptoms alone, such as papilledema and optic atrophy. Others are devoted to diseases alone such as the chapters on abnormality, tumors and the poisons which affect vision. Because of the fact that the book is not broken into parts dealing with these two points of view, it may be necessary for a person interested in the subject to acquaint himself thoroughly with the contents of the volume rather than using it as a reference work. There is an excellent and extensive bibliography which in itself makes the volume a desirable adjunct to the library of the neurologist; and, of course, since it is unique and carefully composed, its value to any practitioner who is interested in neuro-ophthalmology cannot be gainsaid.

Clinical Chemistry in Practical Medicine By C. P. Stewart, M.Sc. Ph.D., Senior Biochemist, Royal Infirmary, Edinburgh, and D. M. Dunlop, B.A., M.D., F.R.C.P.E., Christison Professor of Therapeutics and Clinical Medicine, University of Edinburgh. Second edition. Cloth. Price, \$4. Pp. 372, with 38 illustrations. Baltimore: William Wood & Company, 1937.

This edition is thoroughly revised. The book has been written especially for the man in practice and its usefulness is virtually limited to that group. The authors are practical and conservative in the presentation. They have not attempted a complete discussion of the entire field of applied biochemistry but have limited themselves to the commoner and more generally useful tests. The text covers the subjects of collection and preservation of samples of blood, urine, feces and spinal fluid; basal metabolism; mechanism of neutrality regulation; glycosuria; albuminuria and tests of renal function; analysis of gastric contents; tests of hepatic function and of the cerebrospinal fluid; chemical tests in pregnancy; blood calcium and phosphorus, and the blood sedimentation rate. Technical methods are given in an appendix instead of the text. All the discussions are concise and clearly presented from the point of view of medical practice.

Cases of Attempted Suicide in a General Hospital: A Problem in Social and Psychologic Medicine: A Report on a Local Condition, Including a Survey of 1,147 Records of Attempted Suicide Cases Admitted to the Boston City Hospital. By Merrill Moore, M.D., Assistant Visiting Neurologist, Boston City Hospital. Reprinted from the *New England Journal of Medicine*, Volume CCXVII, Number 8, Pp. 291-303, August 19, 1937. Paper. Pp. 64. Boston: The Author, 1937.

This short report is an extremely interesting one and would well bear perusal by those who have to do with the operation of general hospitals and by psychiatrists. The author has recognized the fact that the increasing number of cases of attempted suicide brought into the Boston City Hospital is well worthy of study. His investigation is not particularly deep—actual mechanisms of suicide or attempted suicide are not analyzed in terms of deep psychiatry, psychoanalysis or even complicated statistical methods, but quite a number of traits are tabulated, charted, and briefly discussed in a competent fashion. Some of these traits are the age distribution, superficial motives such as economic, domestic, health and love problems, method of attempt, frequency of poisons taken by mouth, and other features which are equally interesting and significant. The author, on the basis of the observations, proposes that a large general hospital with "special protective wards" be established where each patient may be given psychiatric care and treatment. The volume is concluded with twenty-eight numbered paragraphs giving a summary of results and recommendations. There is appended to it a good bibliography.

Methods of Tissue Culture. By Raymond C. Parker, Ph.D., Associate in Experimental Surgery, The Rockefeller Institute for Medical Research, New York. With a foreword by Alexis Carrel, M.D. Cloth. Price, \$5. Pp. 292, with 109 illustrations. New York: Paul B. Hoeber, Inc., 1938.

The preface to Dr. Parker's book expresses conservatively the fact that methods of tissue culture have been well standardized and brought down to date in Dr. Carrel's laboratory in the Rockefeller Institute for Medical Research. These methods may be applied in "five major fields of investigation, namely experimental morphology and the study of tumors, viruses, hypersensitivity and immunity." The introduction by Dr. Carrel is an excellent review of the facts pertaining to the origin, purposes, difficulties and possibilities of this method of research as one of the aids in transforming a dry, dead

morphologic concept of life into one dominated by biologic and physical reactions. It is quite evident in Dr. Carrel's review that fresh tissue culture, as a method of study, is still in experimental stages, requiring refinement of technic, carefulness of controlled observation and conservatism in interpretation and clinical application. The body of the book is particularly devoted to methods and apparatus which should be of great value to those interested in repeating experiments and attempting to solve new problems involving cellular growth in all its phases. This book, although small, contains illustrations of instruments, apparatus and photomicrographs which will help greatly the beginner in his work on the culture of both normal and abnormal tissues. There are also 753 bibliographic references, beginning with the first publication of Harrison (1906-1907) to the most recent contributions of 1937.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Right of Surgeon to Discontinue Operation on Encountering Unexpected Risk.—The plaintiff had been afflicted since she was 3 years old "with serious trouble of the head, nose and throat, at times threatening to involve her lungs." In 1929, when she was 9, her family physician referred her to the defendant, who after diagnosing her ailment as an infected left antrum stated that it would be necessary to "make a hole in the mouth and cut away and remove the diseased tissue" and to administer five or six bronchoscopy treatments subsequently "to clear up the chest." The child's mother, however, in the hope that a change of climate might render such treatment unnecessary, postponed the operation, but no relief followed. In May 1931 the defendant was asked to operate, but because of the condition of the child's chest he did not do so until June 22, 1931. Prior to the operation the mother instructed the defendant "to act on his own best judgment" and gave written consent to the operation. After the operation had been proceeding some twenty-five minutes under an anesthetic, the physician "recognized a condition as 'quite dangerous'; in fact she had a crisis of pneumonia." He "deemed it inadvisable to continue with the operation" and made "no attempt to remove the membrane." The child remained in the hospital five days. Then she was taken home and treated by the defendant from time to time. She was given many bronchoscopy treatments until 1933. The mother then dismissed the defendant and employed other physicians. In 1937 the child, by her father as her next friend, brought suit against the defendant for failing to operate as he had contracted to do. The trial court nonsuited the case on the ground, among others, that there was no proof of a breach of the contract by the defendant. The plaintiff appealed to the supreme court of New Jersey.

Looking at the evidence, said the supreme court, there is no doubt that a radical operation on the left antrum was to be performed. That such an operation was performed by the defendant was proved without substantial dispute. The plaintiff contended, however, that the operation agreed on was not completed because the defendant, without right and illegally, refused or neglected to continue it by the removal of the diseased tissue. That contention, in the opinion of the court, was unsound. The undisputed testimony showed that the defendant, in discontinuing the operation, was within his rights and performed his duty to his patient, since he found in the course of the operation that to continue it would endanger her life. Where, as here, the duly authorized representative of an infant patient has selected a physician to perform an operation under anesthesia and has appointed no other person to represent her during the period of unconsciousness, the law will by implication constitute the physician the representative of his patient and will cast on him the responsibility of so acting in her interest that she will receive the full benefit of

his professional judgment and skill to which she is entitled. This implication, which protects the physician while acting within its scope, places no duty on him to perform an operation that involves risks or results of a kind not contemplated. As was said in *Bennan v. Parsonnet*, 83 N. J. L. 20, 83 A. 948:

The question, however, is one to be settled, not by authority, but by reason, and its importance is such that it touches at a vital point the interests of the entire public, any member of which may at any time suffer in life or health by the establishment of a rule that will paralyze the judgment of the surgeon and require him to withhold his skill and wisdom at the very juncture when they are most needed, and when, could the patient have been consulted, he would manifestly have insisted upon their being exercised in his behalf.

Here, continued the supreme court, according to the undisputed proof, the physician was quoted as saying "I started to operate, and there was a condition there which I recognized as quite dangerous. She had a crisis of pneumonia . . . and I deemed it inadvisable to continue with the operation."

The plaintiff next contended that the evidence respecting the contract of the physician presented a question the jury should have determined as to the terms of the engagement. We think not, said the supreme court. There was no ambiguity in its terms, and the interpretation of such a contract is a question of law for the trial judge and should not be left to the jury.

After discontinuing the operation, the plaintiff further contended, the physician was under an obligation to continue it at some future time, both with respect to the removal of the diseased tissue and with respect to the bronchoscopic treatments to clear up the chest. But, said the court, that contention ignores the undisputed facts. The proofs show that the defendant properly continued from time to time to treat the child in both respects for a considerable period, until the child was removed from his supervision and treatment by the mother, who engaged other physicians to continue such treatment. That this action of the mother was against the wishes of the defendant was disclosed by the proof that the defendant reported to the mother, saying "I would still like to go on with the work; the work still remains; the left antrum is still infected. I will continue with the operation," and added, "Since that time the other side has been infected, that is, the right antrum." The rule is, said the court, that whenever, as here, one party to a contract prevents the other from carrying out the terms thereof, the other party may treat the contract as broken and abandon it. Such an abandonment is merely the acceptance of a situation created by the wrongdoer.

For the reasons stated, the supreme court affirmed the judgment in favor of the defendant.—*Hanig v. Orton* (N. J.), 195 A. 812.

Partnerships: Agreement in Restraint of Professional Practice Enforceable.—The plaintiff physicians, as partners, operated a clinic and entered into a contract of employment with the defendant physician, for the period of one year, in which the defendant agreed that he would not engage in the practice of medicine in the community for ten years from the date of the expiration of the contract without the consent of the clinic group. At the termination of an extended period of the contract, the defendant apparently commenced the private practice of medicine in the city, outside the clinic, and the plaintiffs sought to enjoin that practice. The trial court granted the desired relief and the defendant appealed to the Supreme Court of Iowa.

The privilege of a duly licensed physician, said the Supreme Court, to practice when and where he may wish is a right which the courts will zealously protect. The privilege is one, however, which by valid, voluntary contract, a physician may restrict, provided such contractual restrictions are reasonable and not contrary to public policy. In holding that the restrictions in the present case were reasonable and not contrary to public policy, the court quoted, with approval, from 6 Ruling Case Law 805, as follows:

If the restrictions are not otherwise contrary to public policy, they must be held to be valid when they appear to be reasonably necessary for the fair protection of the employer's business or rights, and do not unreasonably restrict the rights of the employee, due regard being had to the subject-matter of the contract, and the circumstances and conditions

under which it is to be performed. This rule seems to be especially applicable to agreements by assistants to professional men. Such agreements enable the employer to instruct his assistant without fear of afterwards having a rival. Few professional men would take assistants and intrust them with their business, impart to them their knowledge and skill, bring them in contact with their clients and patients, unless they were assured that the knowledge and skill imparted and the friendships and associations formed would not be used, when the services were ended, to appropriate the very business such assistants were employed to maintain and enlarge.

The defendant further contended that the original partnership that negotiated the contract with him was dissolved by operation of law by the retirement of one of the partners and that when a new partner was taken in this in effect resulted in the formation of a new partnership which was not a party to the original contract and therefore was not entitled to maintain any action for the enforcement of the restriction contained in it. Without going into the matter of whether this contention would have been sound if timely made, the court said, it is sufficient to say that the defendant was not in a position to raise it after having operated under the new partnership the full time of the written contract and the extended period thereof. No contention of this sort was then suggested by the defendant and he continued his work and accepted pay according to the understanding of the parties. It was too late for the defendant to raise it after he had terminated his services.

The Supreme Court having found no error in the decree of the trial court, its action granting the injunction was affirmed.—*Larsen v. Burroughs* (Iowa), 277 N. W. 463.

Society Proceedings

COMING MEETINGS

- Academy of Physical Medicine, Washington, D. C., Oct. 24-26. Dr. Herman A. Osgood, 144 Commonwealth Ave., Boston, Secretary.
- American Academy of Ophthalmology and Oto-Laryngology, Washington, D. C., Oct. 9-14. Dr. William P. Wherry, 107 South 17th St., Omaha, Executive Secretary.
- American Association of Obstetricians, Gynecologists and Abdominal Surgeons, White Sulphur Springs, W. Va., Sept. 22-24. Dr. James R. Bloss, 418 Eleventh St., Huntington, W. Va., Secretary.
- American Association of Railway Surgeons, Chicago, Sept. 19-21. Dr. Daniel B. Moss, 547 W. Jackson Blvd., Chicago, Secretary.
- American College of Surgeons, New York, Oct. 17-21. Dr. George W. Crile, 40 East Erie Street, Chicago, Chairman, Board of Regents.
- American Hospital Association, Dallas, Texas., Sept. 26-30. Dr. Bert W. Caldwell, 18 East Division St., Chicago, Executive Secretary.
- American Public Health Association, Kansas City, Mo., Oct. 25-28. Dr. Reginald M. Atwater, 50 West 50th St., New York, Executive Secretary.
- American Roentgen Ray Society, Atlantic City, N. J., Sept. 20-23. Dr. Carleton B. Peirce, University Hospital, Ann Arbor, Mich., Secretary.
- Associated Anesthetists of the United States and Canada, New York, Oct. 17-21. Dr. F. H. McMechan, 318 Hotel Westlake, Rocky River, Ohio, Secretary General.
- Association of Military Surgeons of the United States, Rochester, Minn., Oct. 13-15. Dr. H. L. Gilchrist, Army Medical Museum, Washington, D. C., Secretary.
- Central Association of Obstetricians and Gynecologists, Minneapolis, Oct. 6-8. Dr. William F. Mengert, University Hospitals, Iowa City, Secretary.
- Central Society for Clinical Research, Chicago, Nov. 4-5. Dr. Lawrence D. Thompson, 4932 Maryland Ave., St. Louis, Secretary.
- Clinical Orthopedic Society, Nashville, Tenn., and Birmingham, Ala., Oct. 7-8. Dr. H. Earle Conwell, 215 Medical Arts Bldg., Birmingham, Ala., Secretary.
- Delaware, Medical Society of, Dover, Oct. 10-12. Dr. Allan V. Gilliland, Smyrna, Secretary.
- Indiana State Medical Association, Indianapolis, Oct. 4-6. Mr. Thomas A. Hendricks, 23 East Ohio St., Indianapolis, Executive Secretary.
- Inter-State Postgraduate Medical Association of North America, Philadelphia, Oct. 31-Nov. 4. Dr. W. B. Peck, 27 East Stephenson St., Freeport, Ill., Managing Director.
- Kentucky State Medical Association, Louisville, Oct. 3-6. Dr. Arthur T. McCormack, 620 South Third St., Louisville, Secretary.
- Michigan State Medical Society, Detroit, Sept. 19-22. Dr. L. Fernald Foster, 311 Center Ave., Bay City, Secretary.
- Mississippi Valley Medical Society, Hannibal, Mo., Sept. 28-30. Dr. Harold Swanberg, 510 Main St., Quincy, Ill., Secretary.
- Nevada State Medical Association, Reno, Sept. 23-24. Dr. Horace J. Brown, 120 N. Virginia St., Reno, Secretary.
- Omaha Mid-West Clinical Society, Omaha, Oct. 24-28. Dr. J. D. McCarthy, 107 South 17th St., Omaha, Secretary.
- Pacific Association of Railway Surgeons, Los Angeles, Oct. 7-8. Dr. W. T. Cummins, Southern Pacific General Hospital, San Francisco, Secretary.
- Pennsylvania, Medical Society of the State of, Scranton, Oct. 3-6. Dr. Walter F. Donaldson, 500 Penn Ave., Pittsburgh, Secretary.
- Southwestern Medical Association, El Paso, Texas, Nov. 3-5. Dr. Orville E. Egbert, 116 Mills St., El Paso, Texas, Secretary.
- Vermont State Medical Society, Burlington, Oct. 6-7. Dr. B. F. Cook, 154 Bellevue Ave., Rutland, Secretary.
- Virginia, Medical Society of, Danville, Oct. 4-6. Miss Agnes V. Edwards, 1200 East Clay St., Richmond, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Hygiene, Baltimore

28: 1-148 (July) 1938

- Some Biochemical Properties of *Corynebacterium Diphtheriae*. M. Frobisher Jr., Baltimore.—p. 1.
- Types of *Corynebacterium Diphtheriae* in Baltimore, Md. M. Frobisher Jr., Baltimore.—p. 13.
- *Association of *Trichomonas Vaginalis*, Vaginitis and Leukorrhea. J. Andrews, Baltimore.—p. 36.
- Trichomonas Foetus* in Bulls. J. Andrews and F. W. Miller, Baltimore.—p. 40.
- Further Experiments on Passive Immunity of Rats to *Nippostrongylus* Infections. A. C. Chandler, Houston, Texas.—p. 51.
- Immunology of Epidemic Influenza. T. Francis Jr., New York.—p. 63.
- Glycogen Content of Flagellate of Cattle, *Trichomonas Foetus*. Helen M. Stewart, Baltimore.—p. 80.
- Experimental Studies on Course of *Trichina* Infection in Guinea Pigs: I. Minimal Dose of *Trichina* Larvae Required to Produce Infestation of Muscles; with an Account of Potential Productiveness of the Female *Trichina*. H. Roth, Copenhagen, Denmark.—p. 85.
- Studies on Sodium Deficiency: Effects of Sodium Deprivation on Young Puppies. O. Turpeinen, Baltimore.—p. 104.
- Some Uses of the Chick Embryo for Study of Infection and Immunity. E. W. Goodpasture, Nashville, Tenn.—p. 111.
- Infection of Chorio-Allantois of Chick Embryo as Diagnostic Test for Variola. G. J. Buddingh, Nashville, Tenn.—p. 130.
- Quantitative Studies on Glucose Consumption by *Trichomonas Foetus*. J. Andrews and T. von Brand, Baltimore.—p. 138.

Trichomonas Vaginalis, Vaginitis and Leukorrhea.—

Andrews made clinical and parasitologic observations on 239 antepartum patients to determine the incidence of *Trichomonas vaginalis* and local inflammatory symptoms in the vagina. Organisms were more prevalent in Negro women (50 per cent) than in white women (18 per cent) but the incidence of symptoms was virtually the same in the two groups. The coincidence of *Trichomonas vaginalis* and the symptoms (considered separately, collectively or in combination) was no greater than might be expected by chance alone in the group studied. Of all the assortments, the observed coincidence of trichomonads and vaginitis was least likely to be reproduced by chance alone. Further study involving enough cases to permit the separate consideration of the different types of vaginitis in both pregnant and nonpregnant women is necessary to secure statistical evidence on the existence of a significant relationship between the presence of trichomonads and the occurrence of vaginal symptomatology.

American Journal of Pathology, Boston

14: 385-514 (July) 1938

- Implantation Carcinoma of Tubal Mucosa Secondary to Carcinoma of Ovary. J. A. Sampson, Albany, N. Y.—p. 385.
- Behavior of Murine and Human Leprosy in Foreign Hosts. A. W. Sellards and H. Pinkerton, Boston.—p. 421.
- Histologic and Cytologic Studies of Murine Leprosy. H. Pinkerton and A. W. Sellards, Boston.—p. 435.
- Morphologic Variations of Tumor Cells. O. Saphir, Chicago.—p. 443.
- The Matrix of Epithelial Cell Inclusion Body of Trachoma. P. Thygeson, New York.—p. 455.
- The Ability of Lymph to Maintain Viability in "Devascularized" Lymph Nodes. R. L. Holman, Chapel Hill, N. C., and E. B. Self, New York.—p. 463.
- *Residual Infectivity of Primary Complex of Tuberculosis. W. H. Feldman and A. H. Baggenstoss, Rochester, Minn.—p. 473.
- Staining of Acid-Fast Bacilli in Paraffin Sections. G. L. Fite, Honolulu, Hawaii.—p. 491.
- Exstrophy of Bladder with Imperforate Anus, Absence of Greater Part of Small and Large Intestines, Continuity of Duodenum with Colon, Absence of Left Testis, Epididymis and Cord, and Enormous Hydro-Ureter. J. McFarland, Philadelphia.—p. 509.

Residual Infectivity of Primary Complex of Tuberculosis.—Feldman and Baggenstoss utilized the material from sixty-eight human beings who had died by causes other than tuberculosis in an effort to determine the presence of virulent

tubercle bacilli in chronic tuberculous lesions of the lungs and contiguous lymph nodes. The lesions were emulsified and material from the respective subjects was used to inoculate culture mediums and to inject guinea pigs. Tissues from the lesions of the majority of the subjects were studied microscopically and evidence of activity was apparent in a considerable number. The results of the study show that: 1. The lesions of the primary complex of tuberculosis, when definitely encapsulated and sclerotic or caseous or caseocalcercous, seldom contained viable or virulent organisms. 2. The presence or absence of viable or virulent organisms of *Mycobacterium tuberculosis* in the lesions of the primary complex of tuberculosis cannot be established by morphologic appearances alone. 3. The data suggest that in adults endogenous reinfection is unlikely to occur from lesions of the primary complex. 4. The presence of silica in varying amounts is a fairly constant finding in lesions of the primary complex of tuberculosis. In the absence of demonstrable viable tubercle bacilli in the lesions it is suggested that histologic signs of activity are possibly due to silica.

Nonputrid Pulmonary Suppuration.—Sussman reviews the roentgenologic features of the more severe forms of suppurative bronchopneumonia by means of illustrative cases. The report is intended to supplement that of Jachés made to the second international congress of radiology in Stockholm in 1928. Suppurative bronchopneumonia is to be differentiated from gangrenous bronchopneumonia, which is caused by putrefactive anaerobic organisms and which in its localized form represents the early stage of gangrenous putrid lung abscess and in its diffuse form is usually the result of a spread from a similar lesion. Suppurative bronchopneumonia may be caused by a variety of aerobic organisms including certain strains of pneumococci, streptococci, staphylococci and the Friedländer bacillus. The disease may possibly also be caused by certain anaerobic diphtheroids and streptococci. It occurs most often as a complication of purulent sinusitis, whooping cough, measles, influenza and grip, and after the aspiration of foreign bodies and secretions as in postoperative pneumonia. Suppurative bronchopneumonia is also the usual result of infection distal to any bronchial obstruction.

Carcinoma of Uterine Cervix.—Bowing and Fricke feel that the intensive broken-dose method of radium therapy, followed by a course of roentgen treatment, after thorough study and planning of each individual case, offers the best results in the treatment of carcinoma of the uterine cervix. In their series of 1,491 cases, extending over a period of fifteen years, although the great majority of patients (91 per cent) were in an advanced stage of the disease 26.8 per cent lived five or more years in apparently good health following treatment. The possibilities of this form of treatment for early and borderline lesions can be appreciated when it is noted that 69.2 per cent of the seventeen patients with lesions in stage 1 were well at the end of five

years, and 60.2 per cent of those (eighty-five) with borderline lesions were well at the end of five years. This form of treatment requires considerable individual care and cooperation between patient and physician. The fact that there is little risk to the treatment is attested by the fact that the hospital death rate for the entire series was only 1 per cent, the mortality occurring in the group with advanced lesions. There were no deaths during treatment in the early or borderline groups.

Neurogenic Sarcoma. H. Charache, Brooklyn.—p. 275.

Blood Diastase in Diagnosis of Common Duct Stone.—Branch and Zollinger performed the blood diastase index in seventy-five cases of cholelithiasis in order to determine its value as an aid in the diagnosis of stone of the common duct. Twelve stones of the common duct were recovered at the time of operation. The elevation of the index was found of value provided the samples were obtained during or immediately after an attack of biliary colic as the result of a calculus in the common duct. In six of these twelve cases of stone of the common duct there was a definite rise in the blood diastase index, varying in amount from 300 to more than 1,000 mg. per hundred cubic centimeters. These patients were seen immediately after the onset of the attack. In the other six instances, however, a period of four days or more had elapsed and at that time the index was found to be within normal range. In the cases of cholelithiasis alone the index was found to be slightly elevated in ten cases. With one exception, this rise in the diastase was below 250 mg. However, in one case of cholelithiasis associated with acute cholecystitis there was an elevation of blood diastase to 600 mg. Whether a stone was present in this case but was not found at operation cannot be determined.

Comparison of Antiseptics and Germicides.—Dunn compared a few well known agents in respect to their germicidal action toward *Staphylococcus aureus*, Government 209, *Escherichia coli* and *Bacillus subtilis*. The antiseptics used were purchased in the open market except for the alkyl-dimethylbenzyl ammonium chlorides, which were obtained through the courtesy of a pharmaceutical company. As a germicide, alkyl-dimethylbenzyl ammonium chloride was considerably more effective toward *Staphylococcus aureus* at both 20 and 37 C. than the marketed products (tincture metaphen [1:200], tincture merthiolate [1:1,000], hexylresorcinol and pepsodent). In the presence of 50 per cent blood serum, the ammonium compound showed greater efficacy at 20 C. toward *Staphylococcus aureus* than any of the agents with which it was compared (bacili kil, hexylresorcinol, metaphen, merthiolate, pepsodent and zonite). At 37 C. and under similar conditions, the ammonium compound, bacili kil, metaphen and merthiolate were most effective. Tincture metaphen (1:200), alkyl-dimethylbenzyl ammonium chlorides and pepsodent were most efficacious toward *Escherichia coli* at 20 and 37 C. Metaphen was less active than the ammonium compound at 20 C. but was more active than this compound at 37 C. Spores of *Bacillus subtilis* were not destroyed as rapidly or in as high dilution as vegetative cells of bacteria.

Metaphen (1:200) and the ammonium compound (a 1:10 alkaline solution) were most active in destroying the spores. Phenol (1:20) and pepsodent did not destroy the spores in twenty-five hours.

Trends in Public Health. T. Parran, Washington, D. C.—p. 115.

Hyperparathyroidism and Paget's Disease.—Gutman and Parsons made clinical, roentgenologic and biochemical studies on three patients with proved hyperparathyroidism presenting, in addition, certain aspects of Paget's disease (in one the sclerotic changes were in the skull, in one in the pelvis and in the other in the tibia and the skull). The coexistence of the two diseases in these instances would appear to be fortuitous. An alternative explanation has been offered by Albright, Aub and Bauer: If the unknown factor stimulating osteoclastic activity in Paget's disease is present in a patient in subthreshold degree, superimposed hyperparathyroidism, with its generalized stimulus to osteoclastic activity, may make the underlying disease become manifest. Whatever the explanation for these cases, the authors feel justified in concluding that they do not seriously jeopardize the prevailing view that hyperparathyroidism and Paget's disease are distinct and unrelated entities. They serve, however, to emphasize two practical points: 1. Cases of hyperparathyroidism may present isolated areas of bone sclerosis. 2. Appropriate chemical studies should be made even in cases of apparently obvious Paget's disease to exclude the possibility of hyperparathyroidism.

Heparin in Thrombosis.—After studying the effect of heparin in dogs in arterial anastomosis, venous grafts, peripheral embolism, splenectomy and transplantation of organs, Murray and Best administered heparin to 335 human beings in peripheral embolism, splenectomy, postoperative pulmonary embolism, pulmonary embolism with infarcts and phlebitis. Heparin is

not administered for from four to twenty-four hours after operations in order that the normal processes which control bleeding may begin to function. If there is any doubt about oozing or bleeding, the patient is not given heparin. There were only four cases of postoperative hematomas while under the influence of heparin. The hemorrhage stopped when heparin was discontinued and all the patients recovered. As there are no toxic effects, the patients in the wards have received general heparinization. The ordinary intravenous drip is used, and to the saline solution sufficient heparin is added to increase the clotting time of the patient to about fifteen minutes. Usually, heparin is added in the proportion of ten units of heparin to 1 cc. of saline solution. The injection is discontinued when the patient has regained normal activity, i. e., when the factors thought to contribute to the production of thrombosis have ceased to act. This is when shock has passed and the blood pressure and circulation are normal; the incision has healed and is not painful; so that deep respirations are possible; the patient feels well and energetic and moves about actively in bed and can do exercises; distention is gone; the appetite has returned and the gastrointestinal and urinary functions have returned to normal; the chest is clear, and the temperature and pulse are normal. A patient in whom active thrombosis is detected following an operation, during an illness or who has had a pulmonary embolism is probably in grave danger and would probably benefit from the administration of heparin. Until the methods of detecting those cases in which thrombosis is likely to develop are perfected, the group of postoperative cases in which this complication is likely to develop should be treated. The clinical use of heparin in phlebitis, embolism and operations on blood vessels are limited, but experimental evidence, especially in operations on blood vessels, gives strong support in favor of its value. In the suturing of vessels, the repair of aneurysms and arteriovenous fistulas, heparin may be of great assistance in obtaining good results. In blood transfusion heparin can be employed quite satisfactorily instead of citrate. It is useful also in removing blood for the ordinary laboratory tests where citrate or oxalate is commonly used. Other possible fields in which heparin might be useful, but which have not been explored, are coronary thrombosis and cerebrovascular thrombosis.

Plasma in the Treatment of Shock.—During the past year, in order to test the effectiveness of dried plasma in experimental shock with and without hemorrhage and to compare the dried plasma with the other commonly used intravenous fluids, Mahoney produced shock in dogs by cooling the peritoneal surfaces and by trauma to an extremity. The ultimate result of injecting dissolved, processed plasma in shock produced by peritoneal cooling was the same as with the injection of whole blood, but the elevation in blood pressure was more prompt and the improvement in the general condition of the dog was more striking. The blood pressure returned to normal within half an hour after the injection of the plasma and remained stabilized. The dogs regained consciousness, the body temperature returned to normal and the mucous membranes regained their normal color within one hour. In shock produced by trauma to an extremity the response of the blood pressure to plasma was only temporary. In one experiment the dog survived, but with all others the blood pressure increased temporarily and then steadily declined until death occurred. The dissolved, processed plasma has been utilized in treating patients who were in profound shock resulting from burns and from trauma. The number of cases is limited, but the results have been decidedly encouraging, especially with burns. The clinical study will be the subject of a future publication. The dissolved plasma should always be cross matched with the recipient's cells, preferably by the Coca compatibility test for direct matching.

Primary Malignancy of Jejunum and Ileum.—The four cases of primary malignant growth of the jejuno-ileum that Cameron encountered during the last eight years are cited and the reports of 196 similar cases in the literature during the same period are reviewed. Carcinomas outnumbered sarcomas 5:4, and malignant carcinoids 8:1. The average age incidence for these three groups is respectively 51, 48 and 57 years, exclusive of infants and children, who comprise 10 per cent of the sarcoma group and who are almost exclusively males. Two thirds of the primary neoplasms appear in the extremities and

one third in the intervening portions of the jejuno-ileal segment. From 80 to 90 per cent of carcinomas and malignant carcinoids and at least 50 per cent of sarcomas produce mechanical obstruction of the intestine. Infrequently there are neither localizing symptoms nor positive x-ray signs of localized intestinal involvement. Nonobstructive cases present almost insurmountable diagnostic difficulties. Occult blood in the stool is inconstant and frequently of no material value in differential diagnosis. Positive x-ray signs of localized intestinal involvement are essential for a diagnosis of a small intestinal neoplasm. A clinical diagnosis of jejuno-ileal neoplasm is made correctly in approximately one sixth of the cases. A positive clinical and x-ray diagnosis of malignant growth is seldom made and rarely warranted by the conditions found. Approximately two thirds of the cases are operable. The operative mortality is 30 per cent and five year survivals occur in less than 10 per cent.

Arsenical Dermatitis.—Acetarson and related compounds containing pentavalent arsenic are used with increasing frequency in the treatment of infections caused by *Trichomonas vaginalis*. Kesten cites four cases in which localized dermatitis followed the use of one of these compounds and in which the course, the appearance and the distribution of the eruption were strikingly similar. In a fifth case the dermatitis produced was generalized and indistinguishable from that produced by the arsphenamines. These cases are examples of sensitization to a pentavalent arsenical following absorption through the vaginal mucous membrane.

Cutaneous Diseases in Feeble-minded.—Butterworth and Wilson examined the skin of the entire population (1,895 patients) of the Pennhurst State School for the Feeble-minded. There were 780 dermatologic diagnoses made in 654 cases. The incidence of cutaneous diseases and abnormalities was about equal in the two sexes. A total of sixty-eight different dermatologic conditions was observed. Of the total number of diagnoses, 546 were in order of frequency acne vulgaris, nevi, tinea, pyoderma, distended stria, traumatic dermatitis, verrucae, hypertrichosis, perlèche and contagious molluscum. There were fifteen cases of seborrhea and fourteen cases of scabies.

Stain for Spirochetes.—For the last five years in the department of syphilis of the Los Angeles County Hospital Chambers and Scholtz have made clinical use of a staining method (a modification of Dieterle's method developed by Krajian) for the identification of *Spirochaeta pallida* in lesions suspected of being syphilitic. They have used it in nearly 500 cases, the material including tissue from subjects with all types of cutaneous and visceral syphilis, as well as necropsy material. The present communication deals only with its use in cases of primary syphilis. The procedure is essentially the removal of a piece of tissue measuring 2 by 5 mm. from the suspected lesion, placing it in a 10 per cent solution of formaldehyde and sending it to a laboratory for staining. The staining procedure requires less than an hour. The tissue is sectioned by

the rapid freezing technic. The stain has been found accurate in identifying *Spirochaeta pallida* in cases of suspected primary syphilis. Its use in the public health campaign against syphilis is suggested. The stain has been found helpful in many other cases besides those involving suspected primary lesions. It has shown spirochetes in secondary eruptions, in a small number of late cutaneous syphilids, in necropsy material and in surgical specimens.

Acute and Chronic Mediastinitis.—Keefer reports cases which show that an acute abscess or a chronic inflammatory lesion of the mediastinum may occur as a result of a variety of infections. In some cases the process is only part of a more widespread and extensive process, and for that reason it is of interest only so far as the complete diagnosis is concerned. In other cases, however, an abscess is the principal lesion and when recognized it can be treated with a reasonable degree of success. Acute and chronic mediastinal infections are most common in the posterior mediastinum. The common causes of posterior mediastinitis are perforation of the esophagus and suppurative lymph nodes. Abscess of the anterior mediastinum results most often from an infection in the neck or from osteomyelitis of the sternum. The diagnosis of mediastinal abscess depends on (1) the presence of a condition which is capable of producing mediastinal infection, (2) the symptoms and signs of an infection, with local physical signs referable to the mediastinum, and (3) the results of aspiration or exploration. The prognosis is poor, but when the process is localized to a part of the mediastinum that is accessible for surgical intervention the prognosis is better. Chronic fibrous mediastinitis is due to healed or active tuberculosis, syphilis or pyogenic infection. There is often an associated fibrous pericarditis, so that the clinical picture may be that of congestive heart failure due to cardiac compression. Cardiac failure with congestion may also accompany mediastinitis when there is an associated defect of the mitral valve or an aneurysm of the aorta compressing the pulmonary artery. When this is the case the mediastinitis may be latent or may play only a small part in the clinical features.

Diarrhea and Vitamin B₁ Requirement.—Dann and Cowgill carried out experiments on dogs in order to obtain data applicable to an estimation of the vitamin B₁ requirement of patients suffering from diarrhea and on the mode of excretion of this vitamin. They find that diarrhea following adequate storage of vitamin B₁ has little effect on the time required for depletion to the level of anorexia. It seems evident that when the animals are not receiving vitamin B₁ by mouth and the question of failure of absorption due to diarrhea is not involved, the rate of loss of stored vitamin B₁ from the body is not accelerated by diarrhea. In marked contrast were the results when tissue stores were lowered and daily oral doses of vitamin B₁ were administered. When mild diarrhea was induced under these conditions, without exception there was a definite increase in the amount of the vitamin required. This increase ranged from 18 to 82 per cent. The increase can be accounted for by the failure of absorption of the food materials containing vitamin B₁. The concomitant loss of part of the caloric value of the ingested food did not prevent the failure of appetite which is characteristic of vitamin B₁ deficiency. The consistent increase in requirement seen with the daily oral doses was absent when the daily dose of vitamin B₁ was given parenterally. With the exception of one dog, which showed a marked increase, the amounts of rice polishings concentrate

needed to maintain appetite when the dogs were subjected to diarrhea were not significantly larger than those needed in the absence of diarrhea. The average value for the requirement of the vitamin given parenterally was 25 milliequivalents per kilogram daily without diarrhea and 25.5 milliequivalents with diarrhea. The apparently lower requirement of vitamin B₁ by this route as compared to that administered orally is of little significance in view of the wide range of individual variation. The results indicate that no significant amounts of vitamin B₁ are lost by excretion into the intestinal tract when its activity is stimulated and fluid loss is encouraged by diarrhea induced with magnesium sulfate. The possibility of excretion in the bile is by no means excluded. However, if these results are considered in conjunction with those obtained in 1930 (Cowgill, Rosenberg and Rogoff) it appears probable that the chief route of excretion of vitamin B₁ is by way of the kidney. Clinical observations by a number of authors are cited, revealing that avitaminosis, especially of the B complex, is a not infrequent complication of chronic diseases of the gastrointestinal tract in which diarrhea is a symptom. Chronic ulcerative colitis is a conspicuous example of such conditions. A normal person weighing 66 Kg. (145 pounds) should ingest a diet having a vitamin-calory ratio of at least 1.87. The minimal ratio for an adult weighing 35 Kg. (77 pounds) is 1 and for one of 80 Kg. (176 pounds), 2.25. It is advised that, after the minimal vitamin-calory ratio required by the patient has been ascertained and the ratio provided by the diet he is receiving has been calculated, his vitamin B₁ intake should be increased by means of some supplement, so that if the diarrhea is mild he receives a vitamin-calory ratio of at least double the calculated minimum; if the diarrhea is moderately severe the vitamin-calory ratio should be three times the minimum. For the majority of patients showing diarrhea it is preferable to give the extra vitamin in the form of foods rich in vitamin B₁, such as brewers' yeast and wheat germ.

Staphylococcal Food Poisoning.—Roberts and his associates state that from March 9 to 15, 1938, twenty-one persons (five families) were reported as being ill. Investigation supported the incrimination of custard-filled pastry, as the only members unaffected were those who had not eaten the pastry. The interval of time elapsing between the meal and the symptoms varied from one and one-half to four hours. Those who became ill suffered abdominal pain, vomiting and diarrhea. All employees of the incriminated bakery were carefully examined and bacteriologic tests were made. Laboratory studies of the cream-filled pastry showed the presence of *Staphylococcus aureus*. This organism was isolated also from the gastric contents of members of one of the five families while in the hospital, and from the feces. The same organism was isolated from jam pails, pastry bags and milk taken from a can at the bakery.

Staphylococcal Food Poisoning in Montana.—According to Cogswell and his co-workers, on May 26, 1936, information was received by the state board of health of the occurrence of an outbreak of food poisoning in Billings, Mont. The investigation showed that various forms of custard-filled and cream-filled cakes were used by almost all of those who suffered illness. Several cases of illness occurred also in Laurel. Study showed that cases of illness had occurred as early as May 16, both in Billings and in Laurel. The major outbreak, however, occurred during the period May 23 to 26. More than fifty cases were investigated and probably a number of other cases occurred with milder symptoms. The patients suffered an acute illness developing within four or five hours after the infected food was eaten. The majority suffered marked abdominal pain followed by vomiting and frequent bowel movements, in some cases as many as twenty. Examination of the pastry showed the presence of staphylococci in large numbers in the fillings. Reactions typical of *Staphylococcus albus* were obtained. In gelatin stabs a slight cuplike liquefaction occurred. *Staphylococcus aureus* as well as *Staphylococcus albus* strains were recovered from orange rolls. It is evident that both *Staphylococcus albus* and *aureus* were associated in the poisoning. The investigation did not reveal the source of the contamination. On the discontinuance of the distribution of cakes with such fillings, no further cases occurred.

Industrial Dermatoses.—Schwartz points out that it is estimated that industrial dermatitis constitutes more than 65 per cent of all cases of occupational disease reported in the United States and from available records it is estimated that there are about 20,000 patients in the United States with industrial dermatitis of sufficient severity to lose time from work. Actually there are many times this number, because a large majority of cases of industrial dermatitis are not reported even though they may be treated by the plant physician or by the insurance company doctors. The chief active causes of industrial dermatitis differ

in various localities according to the prevailing type of industry. In rural communities plant poisonings are prevalent, whereas in large manufacturing communities the chemical irritants are the chief causes. The actual causes of industrial dermatoses are mechanical and physical trauma, chemical irritants, specific irritants, plants and biologic agents. Some of these various causative factors act as keratin and fat solvents, desiccating or hygroscopic agents, protein precipitants, oxidizers, hydrolizers, stimulators to the keratin-forming cells of the skin or sensitizers. There is no one factor on which a diagnosis of industrial dermatitis can be made. In most instances the appearance of the lesions gives no clue to the irritant. Especially is this the case in the acute and chronic eczematoid types of occupational dermatoses. In applying medication to the lesions, only the mildest form of ointments or lotions should be used. Strong ointments are apt to irritate the skin and cause more dermatitis. Desensitization has not given any encouraging results. The ideal prevention is to safeguard the operation so that injurious chemicals do not come in contact with the skin.

Unidentified Virus Producing Meningitis and Pneumonitis.—Francis and Magill describe an infectious agent which apparently belongs to the class of filtrable viruses but which, on the basis of the evidence at hand, is not identical with any previously known virus. The virus was repeatedly recovered in 1936 from ferrets inoculated with throat washings of patients suffering from an epidemic disease clinically indistinguishable from epidemic influenza. It is impossible, however, to conclude whether the virus is of ferret or human origin. The virus has

multiple tropisms and is pathogenic for mice, ferrets and monkeys of both *Macacus rhesus* and *Macacus cynomolgus* species. Intranasal infection of mice and ferrets causes extensive pneumonic lesions of fatal severity. Intracerebral inoculation of the virus produces in monkeys a lymphocytic choriomeningitis from which the animal recovers, while in mice a rapidly fatal choriomeningitis is produced. Fatal paralysis occurs in a moderate proportion of mice which receive the virus by intraperitoneal or subcutaneous routes, while the remainder become immune to the intracerebral test but not to the intranasal test. Subcutaneous inoculation of mice, monkeys, ferrets, rabbits and guinea pigs causes local granulomatous induration of the skin with enlargement of the regional lymph nodes. Although the new agent possesses many features in common with the virus of lymphocytic choriomeningitis and the virus of venereal lymphogranuloma, cross immunity tests have failed to yield any evidence that it is immunologically related to either the virus of venereal lymphogranuloma or lymphocytic choriomeningitis. For purposes of identification the name virus of acute meningopneumonitis is suggested.

Undulant Fever in the United States.—Beginning in 1927 the United States Public Health Service has received reports of cases of brucellosis from the various states. Only 112 cases were reported in 1927 but by 1937 the number had increased to 2,497. The total number of cases actually occurring is undoubtedly much larger than that reported. About one sixth of the cases reported during 1937 were in Oklahoma. Prior to 1936 few cases were recognized in Oklahoma, but during 1936 ninety-six cases were reported, followed by 431 cases in 1937. Preliminary reports for 1938 indicate that the number of cases will probably be larger than in 1937. The majority of people have no direct contact with *Brucella*-infected animals, and, if all milk were efficiently pasteurized or boiled before being consumed, there would be no brucellosis excepting in those whose work brings them into contact with infected animals or infected carcasses.

Antagonism Between Species of Malaria Parasites.—In combining *Plasmodium vivax* and *Plasmodium malariae* in the treatment of sixteen patients with dementia paralytica,

Mayne and Young found that twelve demonstrated the presence of both species whereas four showed only one species. When the two species of parasites appeared in the peripheral blood stream concomitantly, one rapidly became predominant and the other tended to disappear. There is an apparent antagonistic action of one species against the other. In the mixed infection of *Plasmodium vivax* and *Plasmodium malariae* the predominant species is not always the same. Of the twelve mixed infections, nine showed *Plasmodium vivax* as predominant while three showed *Plasmodium malariae*. Owing to the suppression of one species by the predominant species it seems evident that there are many more cases of mixed infections than are actually reported, especially in surveys in the field under normal conditions, where only a few examinations are made.

Toxicology of Phenylidichlorarsine.—An examination of the results that Sayers and Dudley obtained from sixteen men subjected to cutaneous tests of the vesicant qualities of 1 per cent oil mixtures of phenylidichlorarsine shows that there is a marked difference in the susceptibility of certain persons to their action. Three men showed definite initial cutaneous reactions, seven gave no subjective or objective symptoms of reaction, while six showed varying degrees of susceptibility from moderate to slight. It seems probable that preliminary cutaneous tests would be helpful in determining those workers who would have a marked tendency toward cutaneous reactions when working in wood-treating plants. By selecting workers showing no cutaneous reaction, many of the untoward effects of the oil mixtures of phenylidichlorarsine could be prevented. Protection is possible by spreading a salve, prepared from petrolatum and ferric hydroxide, over the exposed cutaneous areas of the worker. Impregnated wood free from surface oil causes no reactions when applied to the skin of men for as long as one hour. Steaming after impregnation removes surface oil and renders the oil mixture in the body of the wood nonvesicant to rabbits.

Action of Sulfanilamide.—In an effort to repeat the observations of Osgood, Kemp used two sets of hemolytic streptococci: one set of four cultures from a group of patients on whom sulfanilamide seemed to have exerted a most beneficial effect; the other (four cultures) from patients who had received vigorous treatment with sulfanilamide without beneficial effect, all dying of their streptococcal infection. To test the antihemolytic effect of the drug, blood agar plates containing sulfanilamide in dilutions of 1:1,000, 1:10,000 and 1:100,000 were

seeded with the foregoing cultures. No significant differences could be observed between these plates and plates containing no sulfanilamide. As a test of the antitoxic qualities of the drug, an attempt was made to see if dilutions as high as 1:1,000 would neutralize the streptococcus toxin used for the determination of susceptibility to scarlet fever, the Dick toxin. Fifteen positive reactors were discovered in testing seventy-two medical students and these reactors were inoculated simultaneously with Dick toxin in the skin of one forearm and with a mixture of sulfanilamide 1:1,000 and Dick toxin in the skin of the other forearm. The two sites of injection displayed the positive reaction at the same time and with the same intensity, there being no neutralization of the toxin by the drug at 1:1,000. Concentrations as high as 1:3,500 failed to neutralize the fibrinolytic qualities of the cultures, even when amounts as small as 0.2 cc. of a twenty-four hour broth culture were used with the standard amount of serum used in such tests. The same high concentrations of sulfanilamide did not interfere with fibrin formation in control tubes carrying no streptococci. Whatever the action of sulfanilamide, the in vitro methods fail to reveal it. If the beneficial effects of the drug are as real as they are apparent, the mode of action must be sought for in living tissue as Osgood has tried to do. Whatever its reactions there, it would not appear that these reactions belong to the category of immune substances. The immune substances, antibodies, are characterized by their reactions both in vitro and in vivo. Since the drug failed to neutralize the streptococcus toxins (hemolysin, dermatoxin and fibrinolysin) and since streptococcus antitoxin will neutralize these toxins both in vivo and in vitro, it seems reasonable to conclude that sulfanilamide is not an antitoxin, whatever its mode of action.

Air Conditioning and Infections of Respiratory Tract.—Windham states that pathogenic effects of catarrh and colds may be linked to the autonomic nervous system because when climatic changes are frequent and severe the autonomic nervous system is fatigued. Long exposure to cold produces dryness of the mucous membrane and leads to susceptibility to infections of the upper part of the respiratory tract. Climates and diseases are interrelated in an active role, for in regions of highly changeable temperature and pressure the population is usually badly affected with chronic respiratory and arthritic troubles, sinusitis, chronic bronchitis, tuberculosis and rheumatoid arthritis. With the man-made climate or weather in proper air conditioning, the patient can be placed in rooms suitable to his particular disease and expect to get maximal results in the minimal time. For general comfort the temperature should be kept from 10 to 15 degrees below the outside temperature in summer, with from 50 to 55 per cent relative humidity. Rooms for arthritic patients should maintain a temperature of from 80 to 85 F., from 35 to 30 per cent relative humidity; for tuberculosis 68 F. and from 40 to 50 per cent relative humidity; for common colds and respiratory infections from 70 to 72 F. and 55 per cent relative humidity. Patients having infections of the respiratory tract placed in air conditioned rooms have shown a much more rapid and satisfactory recovery, and no patient placed in air conditioned rooms has acquired any colds or other respiratory disorders.

Trichophytic Granuloma.—Smith describes the cases of two boys with a peculiar granulomatous eruption involving the scalp, face, limbs, groin, penis and buccal mucosa, with a prolonged course, little if at all influenced by treatment and ending in recovery with slight scarring. The finding of mycelium in sections from a recent lesion in the second case was the only positive suggestion as to the cause. The failure to respond to massive doses of potassium iodide was against a diagnosis of blastomycosis or sporotrichosis. The mycelium suggests a hyphomycetes rather than a blastomycetes, and no torulae could be detected, but the clinical appearances, and particularly the severe involvement of the buccal mucosa, with ultimate scarring, were unlike those of any deep trichophytia which the author has seen.

Chronic Mastitis and Breast Cancer.—Handley discusses the histories of five sisters with cancer of the breast observed for nineteen years. Their mother died at the age of 69 of cancer of the liver and her mother at the age of 37 of abdominal cancer, probably gastric, since it was attended by persistent vomiting. Five separate breast cancers in the family have been treated with radical operation—four by the author and one by Warwick; and in addition two simple mastectomies have been done—one for incipient cancer, the other for precancerous mastitis. Two of the sisters have died of breast cancer and three are well at the time of writing. The two sisters who died survived operation eleven and nine years, respectively. The results offer encouragement that routine mastectomy for chronic mastitis can be safely rejected in favor of roentgen treatment followed by periodic examination, with mastectomy in reserve if danger signals show themselves. Though the author believes radiation to be a valuable prophylactic, it cannot in all cases be an efficient substitute for surgery.

Uterine Bleeding Treated with Progesterone.—Macgregor presents the results of thirteen cases of irregular uterine bleeding, essentially associated with a disturbance of the pituitary-ovarian mechanism, treated with progesterone, 5 mg.

given daily. In ovular bleeding the treatment was given two or three days before the expected anomalous bleeding, the aim being to maintain endometrial stimulation during the time of ovulation and thus tide over the period when the estrogenic content of the blood was lowered. In hemorrhagic metropathia progesterone may be given at any phase. During the bleeding stage 5 mg. was administered daily until the bleeding was controlled. During the amenorrheic phase 5 mg. was given daily, the total dosage amounting to from 25 to 30 mg. Three of the five patients with the ovular type of bleeding have had regular menstruation for the last eighteen to twenty-two months. One patient had three regular periods after cessation of therapy; she then became pregnant and aborted at the end of the second month of gestation. The other patient, though not completely well, has now only a brownish discharge, whereas formerly she had frank hemorrhage for a few days between every two periods. In four of the seven cases of anovular bleeding menstruation became normal in duration and periodicity, in two of which there has recently been a recurrence of the irregularity. In the remaining three patients the uterine endometrium was examined microscopically before and after treatment and as a result of the treatment the hyperplastic endometrium has been changed into a pseudosecretory phase. These patients have only recently been under treatment and two have had two normal periods. Comparatively few favorable results follow the indiscriminate use of progesterone therapy.

Thyroxine Therapy in Otosclerosis: Report of Forty-Two Cases. M. A. Goldstein.—p. 444.

Facial Palsy from Intratemporal Epidermoids.—During the last five years Jefferson and Smalley encountered six cases in which a slowly progressive facial palsy has been proved to be due to an epidermoid lodged within the temporal bone. No infection was present in any of the cases, and three patients had never had otitis media. All, however, were deaf to a greater or lesser degree on the side of the palsy, and this fact led to a painstaking investigation of the temporal bone for a possible causative lesion. The facial paralysis had in each case taken several months to develop and was in that respect totally unlike Bell's palsy. The syndrome is related to the pure pressure effect of epidermoids (as is the case with the intradural variety) and not to the well known septic condition of the ordinary cholesteatoma. The nature of the epidermoids is discussed and the view is held that most, if not all, of the present series were of embryonal origin.

*Antibacterial Action in Vitro of 2-(p-Aminobenzenesulfonamido) Pyridine on Pneumococci and Streptococci. A. Fleming.—p. 74.

Bactericidal Action of 2-(p-Aminobenzenesulfonamido) Pyridine.—Fleming performed experiments to see whether 2-(p-aminobenzenesulfonamido) pyridine has any action on bacteria in vitro and whether any reasonable explanation could be

given of its curative action. The drug has no deleterious action on leukocytes in concentrations up to 1:8,000, which is stronger than is likely to be attained in the body. The use of de-leukocytized blood gives the true antibacterial effect of the chemical, for such blood has no bactericidal power toward the pneumococcus. The test organism was a pneumococcus (type 23). Infected de-leukocytized blood was mixed with equal volumes of various dilutions of the drug in physiologic solution of sodium chloride and incubated in slide cells. In an implant of 100 cocci all the cocci survived and grew out, but there was a definite inhibition of growth as was shown by the size of the colony. In a concentration as low as 1:256,000 the colonies were smaller and in 1:128,000 they were in twenty-four hours only minute. In de-leukocytized blood, therefore, the drug has no power of killing pneumococci, but it has an evident bacteriostatic power even when present only in small amount. Defibrinated blood-containing its full complement of leukocytes was capable of preventing the growth of large numbers of pneumococci. A comparison of experiments with defibrinated and de-leukocytized blood brings out that: 1. Normal human defibrinated blood can prevent the growth of large numbers of pneumococci. 2. If the leukocytes are removed from such blood, all the pneumococci implanted grow out freely. 3. In de-leukocytized blood 2-(p-aminobenzenesulfonamido) pyridine has no bactericidal power but delays the growth of pneumococci. 4. In normal human blood the compound completely prevents the growth of pneumococci even when present only in high dilution. Experiments exactly similar to the foregoing were made with blood and de-leukocytized blood implanted with a group A hemolytic streptococcus ("Richards") and it was found that with hemolytic streptococci, as with pneumococci, the drug does not kill the organisms but delays their growth and (probably for this reason) inhibits the development of hemolysis. In defibrinated blood containing its full complement of leukocytes with an implant of 2,900 "Richards" streptococci per cell there were in the control cell large confluent areas of hemolysis, and it was obvious that a considerable number of colonies of streptococci had developed. In the weakest concentration only four small colonies were visible, and in 1:64,000 no growth occurred even after the cells had been incubated for several days. If blood is rendered "immune" by the addition of some specific immune serum, the apparent effect of the chemical is enhanced. It is suggested that, to obtain the best results with the drug, patients should be immunized actively or passively.

*Chemotherapeutic Experiments on Virus of Lymphogranuloma Inguinale in Mouse. F. O. MacCallum and G. M. Findlay.—p. 136.

Postpartum Necrosis of Anterior Pituitary.—Sheehan and Murdoch encountered fifty-four patients who had only a moderate anterior pituitary insufficiency and certain of these showed a definite improvement without specific treatment. This improvement was sometimes spontaneous and sometimes the result of a subsequent pregnancy. Whereas spontaneous improvement is uncommon and rarely great, there is nearly always a pronounced and often complete recovery if the patient becomes pregnant again. The improvement in the general health is usually quite obvious when the patient is only a few months pregnant. If the delivery is normal the improvement is maintained permanently. Certain conditions, such as retained placenta, which have caused hemorrhage at the original delivery may recur in a subsequent delivery and lead to serious collapse again. If this happens the improvement due to the pregnancy may be partly or completely lost, presumably as a result of a further necrosis. Apart from this obvious cause there are occasional cases in which the condition of the patient does not improve after a normal pregnancy and delivery; it is not clear whether the failure to respond is due to the pituitary itself or

to the related endocrine glands. These are exceptions; the normal result of subsequent pregnancy is a striking symptomatic recovery. The most satisfactory explanation of the improvement appears to be that the part of the anterior pituitary which escaped the original necrosis undergoes normal physiologic hypertrophy during pregnancy but that it does not involute after the delivery to the size that it was before the onset of the pregnancy. The rational treatment of cases of pituitary insufficiency due to postpartum necrosis is to encourage a further pregnancy, despite the natural disinclination of the patient. The utmost care must be taken to avoid any hemorrhage or collapse at delivery; any obstetric complication which can be anticipated must be avoided. Blood donors must be present and all arrangements must be ready for immediate transfusion at delivery.

Chemotherapeutic Experiments on Virus of Venereal Lymphogranuloma.—MacCallum and Findlay infected intracerebrally between 200 and 300 mice with two strains of the virus of venereal lymphogranuloma. The compounds employed in treatment have been *p*-aminobenzenesulfonamide (sulfanilamide), which has been given subcutaneously suspended in olive oil, *p*-benzyl-aminobenzenesulfonamide (proseptasine), given by mouth, and a dextrose derivative of 4:4'-diaminodiphenylsulfone, which has been given both subcutaneously and orally. With both the sulfanilamide and the dextrose derivative a considerable proportion of the treated mice were saved. The first possibility that suggested itself was that some intercurrent bacterial infection was responsible for the death of the control mice and that it was this bacterial infection, rather than the virus disease itself, which was being controlled by the drugs. However, cultures of the brains of control and treated mice failed to show any growth on ordinary bacteriologic mediums, so that the evidence is in favor of the view that it is the virus itself which is being acted on. At present it is impossible to suggest a reason why the virus of venereal lymphogranuloma is susceptible to chemotherapeutic action while so many other viruses are not susceptible. Oakley (1938) found that, provided the virus inoculum was small, the dextrose derivative of 4:4'-diaminodiphenylsulfone had a slight but significant action in curing mice infected with influenza virus.

*Injection Treatment of Primary Hydrocele and Spermatocoele. A. G. S. Cooper.—p. 19.

Injection of Hydrocele and Spermatocoele.—During the last six years Cooper has treated eight cases of chronic primary hydrocele and two of spermatocoele by injections, with satisfactory results. For the injection, quinine and urethane, quinine dihydrochloride and Moresin's fluid have been employed. The latter solution has yielded the best results. Moresin's fluid consists of equal parts of phenol, glycerin and alcohol. In treatment, the technic consisted of simple paracentesis with a serum needle, aspiration of as much hydrocele fluid as possible, and injection of Moresin's fluid through the same needle, approximately 1 cc. being used for each 20 to 30 cc. of fluid aspirated, up to a maximal dose of 40 cc. A preliminary superficial injection of local anesthetic was always administered. The injected fluid was massaged into every part of the sac of the hydrocele and a suspensory bandage was applied. Almost invariably a secondary accumulation of fluid occurs, and this should be aspirated ten days after the injection, without further treatment. Most of the patients have been under observation for years and no recurrences or other disabilities have been observed or reported. The efficacy of injection treatment in the classic type of long-standing hydrocele with excessively thickened parietal tunica after numerous tapings is doubtful.

Diagnosis of Acute Leukemia. P. Lambin.—p. 1156.

*Epidemiology and Prophylaxis of Icterohemorrhagic Spirochetosis or Weil's Disease. A. Hougardy.—p. 1163.

Action of Iccoral After Spinal Anesthesia. R. Schockaert and J. Lamillon.—p. 1173.

Spirochetal Jaundice.—Hougardy thinks that the physician encountering a case of infectious icterus will more often than formerly think of the possibility of spirochetal jaundice. He reviews the principal elements in the pathogenesis of ictero-hemorrhagic spirochetosis, discussing the animal vectors of *Leptospira* and the part played by water in the transmission. Further, he discusses ictero-hemorrhagic spirochetosis as an occupational disease in sewer workers and miners and the transmission of the disease by pigs, which explains the occurrence of the disease in butchers. He stresses the importance of the supervision of bathing establishments, particularly on rivers, in which protection against rat infestation is essential. He discusses rat proofing of buildings and deratization by mechanical and toxic means. The cooperation of the public should be enlisted.

*Several Toxic Volatile Industrial Solvents. D. Glibert.—p. 1189.

Partitioning-off or Exclusion of Small Pelvis from Abdominal Cavity. J. Rouffart-Marin.—p. 1203.

Toxic Industrial Solvents.—Glibert thinks that, because of the growing use of volatile solvents in industry, physicians are likely to encounter some of the harmful effects which may be caused by them. There are a great number of these industrial poisons but in this paper the author discusses only the most dangerous and the most widely distributed of the toxic solvents, admitting nevertheless that other volatile solvents have proved injurious under some exceptional circumstances. He does not review in detail the dangers of benzene and of its homologues toluene and xylene since the harmfulness of these highly toxic bodies is well known to physicians. He also omits from this discussion carbon disulfide, the acetone group and others. He gives his attention chiefly to the substances of the ethane and ethylene group; tetrachlorethane, pentachlorethane, dichlorethylene, trichlorethylene and perchlorethylene. He shows that in estimating the toxicity of volatile solvents it is necessary to take into consideration several factors such as the origin, the degree of purity and the instability. He points out that industrial benzene for instance is not a definitely defined substance but is a chemical mixture of varying compositions. Its composition depends in part on the nature of the petroleum from which it is extracted, because some crude petroleum contain more of one kind of hydrocarbons and others contain more of another type of hydrocarbons. The author further discusses the inexactness of the factors on which is based the theoretic evaluation of the toxicity. He shows that the experimentally established toxicity often differs considerably from the one calculated on the basis of a formula and stresses that in estimating the harmfulness of a volatile industrial solvent it is necessary to take into account the particular circumstances under which it is used: the tension and density of the vapor, the temperature necessary for its use, the evaporation in the air, the more or less extended use of the product and the possibility of recuperation for the worker. He discusses in detail each of the aforementioned volatile solvents of the ethylene and ethane group and then classifies these and the other solvents (not discussed) into four distinct categories. Reviewing the literature on this problem, he directs especial attention to the publication of the Medical Research Council on "Toxicity of Industrial Organic Solvents."

*Surgical Treatment of Permanent Arterial Hypertension: Its Indications by Anesthetic Infiltration of Splanchnic Nerves. F. Paliard and P. Etienne-Martin.—p. 433.

Surgical Treatment of Hypertension.—Paliard and Etienne-Martin point out that if failures are to be prevented in the surgical treatment of arterial hypertension it is important to determine beforehand whether the surgical treatment will be effective. They briefly review the present status of the surgical treatment of permanent arterial hypertension. They

cite four different types of interventions: (1) adrenalectomy either on one side (left) or partially on both sides, (2) splanchniectomy on the left side, which can be bilateralized for the first and second lumbar ganglions, (3) a mixed operation, that is, adrenalectomy on one side and splanchniectomy on the other, and (4) renal enervation. The authors reject the anterior radicotomies of Adson and Craig, which they regard as too mutilating, as well as thyroidectomy, in which failure seems certain. After pointing out that failures might entirely discredit surgical interventions for hypertension, they describe the clinical histories of three cases in which anesthetic infiltration of the splanchnic nerves caused temporary cessation of the functional disturbances. In summarizing their observations on these three cases they say that the anesthetic infiltration of the splanchnic nerves deserves to be extended in hypertension, because it serves two ends: 1. It has a temporary therapeutic effect in that it counteracts some of the grave subjective symptoms, and if it reduces the hypertension it removes the immediate danger of a grave vascular accident. 2. The greater importance lies in the fact that the infiltration, as a physiologic section of the nerves, helps in deciding the surgical intervention. If this physiologic section of the splanchnic nerves causes a reduction in the tension, the surgical intervention is indicated; if, on the other hand, it fails to do so, surgery is contra-indicated.

*Results of Treatment of Certain Articular Fractures by Infiltration with Procaine Hydrochloride and Immediate Active Mobilization. P. Branzan and E. Blum.—p. 417.
Perforated Ulcers of Stomach and Duodenum. B. Herzberg.—p. 436.

Procaine Hydrochloride and Mobilization in Articular Fractures.—Branzan and Blum resorted to infiltration anesthesia only after exact roentgenologic examination of the fracture. In making the infiltration they employ a 1 or 2 per cent solution of procaine hydrochloride without epinephrine. They inject the contents of a syringe of 10 cc. capacity in or near the site of the fracture. The diffused liquid blocks all nervous passages. Contracture and pain disappear instantaneously if the injection is made exactly into the fracture. In the course of the first week the infiltrations are made daily. After that they are given at intervals of two or three days. Depending on the nature of the fracture, the member may be placed in a sling for the first few days or may be left completely free. Staying in bed is necessary only if the fracture is accompanied by such disorders as shock or cerebral concussion. After clinical consolidation is accomplished, the infiltrations are made into the regions indicated as painful by the patients. The authors describe and illustrate the histories of eight cases. The value of this therapeutic method can be estimated by the roentgenograms of the bone lesions and by the photographs of the functional results. As the ideal indications for this method the authors mention (1) the partial fractures of the elbow (epitrochlear, olecranon, head of radius), (2) fractures of the upper end of the humerus in aged subjects, (3) partial fractures of the head of the humerus, complicating the dislocation of the shoulder in patients of all ages, (4) partial fractures of the scapula, (5) fracture of the clavicle without or with slight dislocation in adults and especially in aged persons, (6) fractures at the lower end of the humerus or radius, when reduction is not necessary, especially when the subjects are aged or obese, and (7) fractures of the carpus or metacarpus without dislocation. As regards the lower extremities, the indications for this treatment are rare. However, it has been employed (1) in fractures of the kneecap without dislocation, (2) in certain partial fractures of the tibial disk in aged subjects and (3) in fractures of the tarsus without dislocation and in metatarsal fractures.

*Synthesis of Purines in Patients with Gout: Remarks on Effects of Apuric Diet. F. Coste, A. Grigaut and M. Lamotte.—p. 1129.
Effusions in Extrapleural Pneumothorax. O. Monod, J. Garcia-Bengochea and P. Bruce.—p. 1131.

Purines in Gout.—Coste and his associates studied the effects of an apuric diet in patients with gout. They give a list of foods excluded from the diet and a list of permitted

foods. The diet excludes as much as possible all nucleoproteins and purines of animal and vegetable origin. Of the thirty-four patients who were subjected to the diet, some were observed for several years. In the majority of the patients with gout, the plasmatic uricacidemia and particularly the globular uricacidemia was greatly reduced. The regimen, which is referred to as the apuric standard diet, apparently leads at first to a reduction in the excretion of urates in the urine, but when it is prolonged there generally results an augmentation of uraturia in relation to the increased figures before the diet was begun. It was observed in eleven patients that, after from six weeks to twenty-four months of the apuric standard diet, the daily uratic excretion remains rather high. In the majority of cases the apuric standard diet produces a considerable amelioration, provided it is continued for a sufficient length of time. Often the improvement is such that the attacks of gout are completely suppressed. On the whole, the diet is well tolerated; in the majority of patients it produces neither fatigue nor emaciation. It has been demonstrated that adults with gout, when submitted to a diet without purines, continue to synthesize purines in considerable quantities; this does not result in a noticeable impairment of the organism; it must be admitted that there exists in these patients with gout a puric synthesis from the proteins or amino acids contained in the foods or in the tissues. Nevertheless, the restriction of the alimentary nucleoproteins results in an appreciable decline in the plasmatic and globular uricacidemia and in a regression or complete suppression of the attacks of gout. The addition of nucleoproteins of vegetable origin to this standard diet exerts a variable, often a slight influence on the uratic elimination and on the uricacidemia; in one patient it provoked the return of painful crises, in others it was well tolerated. It remains to be determined whether the therapeutic effects of the apuric standard diet results from the suppression of the nucleoproteins and purines or from the suppression of alcoholic drinks or from both these factors. The authors are of the opinion that both factors play a part.

Question of Infection of Accidental Wounds. F. Lang.—p. 910.
*Clinical Observations in Measles. P. Robert.—p. 914.

Measles.—Robert reports observations which he made in the course of an epidemic of measles during the winter of 1936-1937. He gave especial attention to the diagnostic value of the leukocytic blood picture, to the vitamin C metabolism and to the oral bacteriologic flora. He studied the white blood picture in fifty-three patients with typical uncomplicated measles and found that, contrary to the statements in some textbooks, there is no typical blood picture during the exanthem of measles. In one third of the cases studied the classic leukopenia which supposedly characterizes the severest stage was missing. Moreover, in about 50 per cent of the cases it was impossible to detect a disappearance of the eosinophils during the stage of eruption. The appearance of numerous monocytes at the time of the exanthem could be corroborated. The author regards as especially noteworthy in this material the unexpected appearance during the exanthematic period of numerous plasma cells. Since he studied only the diagnostic value of the leukocytic blood picture he disregards the post exanthematic changes in the blood. In fifteen of the patients with measles he made protracted vitamin C tolerance tests and detected a greater or lesser deficit of vitamin C in twelve. He says further that at the clinic in Basel the examination of oral bacteriologic flora is a routine measure at the time of hospitalization and at the time of discharge for all patients with measles and with scarlet fever. It was found that the oral flora of patients with measles is characterized by a predominance of white and yellow staphylococci. There was no essential difference between the oral floras at the time of hospitalization and of discharge, or between the oral floras of the cases with or without complications.

Medical Treatment of Typhoid. F. Arocena.—p. 149.

Staphylococcus Toxoid in Diabetes.—Richeri and Gómez state that partial immunity should be induced in diabetes by the administration of staphylococcus toxoid in order to prevent staphylococcal pyogenic infection, which frequently develops in the course of diabetes. They determined the amount of antibodies in the blood serum of seventeen patients who had diabetes before, during and after treatment with staphylococcus toxoid. The treatment consisted of four subcutaneous injections of 0.1, 0.2, 0.5 and 1 cc. of a toxoid preparation of the Instituto Nacional Bacteriológico of Buenos Aires, which were given at intervals of four days. The antitoxic values of the blood serum were shown by the concentration of antibodies in the serum, which were calculated from the inhibition of a standard staphylococcus toxin by the blood serum in the presence of erythrocytes of rabbits used as reagent indicators for hemolysis. The authors found that the mechanism of immunity in diabetes is normal and that the administration of staphylococcus toxoid to the patients stimulates the production of specific antibodies. The immunity induced by the treatment with staphylococci lasts more than three months.

Complete Inversion of Uterus. C. Spyropoulos.—p. 510.

Freshening of Wounds.—Heller shows that Friedrich's term "anfrischung" or freshening of wounds has been misunderstood and has led to therapeutic errors. Having worked with Friedrich for many years, he tries to clarify Friedrich's stand and so avoid further misunderstanding. He emphasizes that Friedrich employed suture of wounds only after complete excision, and that in case of incomplete excision he left the wounds open and drained them; that is, Friedrich recommended two ways for the surgical prevention of the infection of wounds: (1) the complete excision with suture of the wounds within the first six hours, in order to prevent an infection, and (2) the open treatment of the wound in which there was danger of infection; that is, in which complete excision was impossible. The author says that whereas the first method is now of slight practical importance, it having been abandoned, the second method is important and is still in use. He thinks that misunderstandings, such as the impression that Friedrich recommended primary suture for incompletely excised wounds, might have been avoided had Friedrich refrained from using the indefinite term "freshening" and had used excision instead. The author shows that, in view of the increasing number of traffic accidents, this problem of the prevention of wound infection is of great importance. He also cites observations that were made during the war, particularly as regards the development of gas edema. He hopes that Friedrich's unfortunate term "freshening," which has become linked with the idea of primary suture of wounds, will be abandoned. This would be no loss, since the method is no longer in use. The term "surgical care of wounds" which is now generally applied is better. To what extent it is necessary to keep a wound open following the surgical toilet, or whether a partial closure is permissible, depends on the seriousness of the injury and on the type of the infection that must be feared. The more severe are the lacerations of the tissues, the more the wound is soiled and the more dangerous is the infectious material, the more urgent it is that the wound remain open; it may even be necessary to open the wound wider. The author further discusses the serologic prophylaxis of tetanus and of gas gangrene, pointing out that seroprophylaxis has replaced antisepsis. The use of

serum for gas gangrene is not reliable as yet and a thorough surgical toilet of the wound is the most important factor in the prevention of gas gangrene. All necrotic portions must be carefully removed. If the work of the surgeon fails in this respect, the efforts of the serologist will likewise be in vain.

Work Test in Electrocardiographic Diagnosis of Angina Pectoris. A. Falcão.—p. 347.

Gastroscopic Investigations in Pernicious Anemia.—Lühr and Gülzow point out that the increased protein content of the gastric juice of patients with gastritis has received considerable attention in recent years. Methods have been developed for the determination of the protein content of the gastric juice and increases have been observed in acute toxic gastritides as well as in a certain number of chronic gastritides. The stomach of patients with achylia has a rich bacterial flora, the digestion takes place under abnormal conditions and often there exists a deficiency of secretion. It was suggested by Katsch that the increased protein values of achylia are partly simulated and partly real. In the achylia concurring with pernicious anemia there nearly always exists an increased protein content and the question arose whether this increase is simulated or whether gastritic changes play a part. The cause of the secretory insufficiency of pernicious anemia is still in dispute; some maintain that the degenerative atrophy of the gastric mucosa is the primary condition, while others ascribe the atrophy to a gastritis. The authors decided to make gastroscopic studies on patients with pernicious anemia, although they are aware of the fact that the increase in the protein content of the gastric juice and the gastritis do not take a parallel course. A review of the literature on gastroscopy in pernicious anemia indicated that a total atrophy of the gastric mucosa is regarded as characteristic for pernicious anemia. The authors subjected a number of patients with pernicious anemia, in whom fractionated withdrawal of the gastric juice had disclosed an increase in the protein content, to gastroscopy. Six of these cases are described in detail. Besides atrophic processes, the authors discovered acute and chronic gastritic processes. The authors agree with those investigators who believe that gastritis plays an important part in the pathogenesis and in the course of pernicious anemia and oppose those who regard a "pure" atrophy of noninflammatory origin as characteristic for pernicious anemia. The gastroscopic observations complement the other material on this problem. The authors think that the increased protein values of the gastric juice of patients with pernicious anemia are probably partly caused by the gastritis.

Tonsils in Hodgkin's Disease.—Bingold points out that Hodgkin's infectious granuloma usually develops slowly and insidiously. Swelling of the cervical glands and less often of the axillary and inguinal glands, together with emaciation, call attention to the seriousness of the disease. Whereas hyperplasia of the cervical glands is quite frequent, it has been stated repeatedly that infectious granuloma does not involve the mucosa of the pharynx and of the tonsils. Although it is generally conceded that the port of entry is in the oral cavity, there are authorities who maintain that in Hodgkin's disease, in contradistinction to other lymphocytomas, the tonsils are not involved or that such an involvement is extremely rare. The author, however, observed cases in which tonsillitis and Hodgkin's infectious granuloma did not merely concur but in which the infectious granuloma attacked the tonsils. Moreover, careful anamneses revealed that in some cases a tonsillitis had been the beginning of the infectious granuloma. This tonsillar process may subside again, although some symptoms may remain until the infectious granuloma becomes manifest. The author describes the clinical histories of several cases in which the tonsillar symptoms predominated. In one of the patients

observed by him the characteristic symptoms of infectious granuloma were lacking, and not until the tonsils were subjected to microscopic examination was it possible to determine that the process was an infectious granuloma. The incipient infectious process of the tonsils may subside again, but how often this takes place is not known. Moreover, it is possible that the infectious granuloma is at first only a local disorder. Cases reported by Görke, Putschowsky and Wulstein seem to suggest this, because three years after radical treatment the patients were free from relapse. The author thinks that his observations stress the importance of a careful microscopic examination of extirpated tonsils in order to detect signs of Hodgkin's disease. He hopes that if evidence of this disease is thus found it might be possible to arrest a perhaps still local process by means of radical surgery and energetic roentgenotherapy and prevent a generalization of the disease.

Gordon Test in Diagnosis of Hodgkin's Disease.—Sachs and Steffel report their experiences with Gordon's test in the diagnosis of Hodgkin's disease. They used Gordon's method of intracerebral injection into rabbits: on material from patients in whom Hodgkin's disease had been histologically demonstrated, on material from patients with disorders other than Hodgkin's disease and on material from doubtful cases. On the basis of their observations they reach the conclusion that when the lymph node is still in the hyperplastic stage, that is, before the development of the typical granulation tissues, Gordon's test is of value for the diagnosis, because it is already positive at a time when the histologic diagnosis is not yet possible. It makes a diagnosis possible in cases in which the only lymph node available for exploratory excision does not yet show the typical granulation tissue. Moreover, it avoids the necessity of repeated exploratory excisions in cases in which, although several lymph nodes are available, the exploratory excision was made on one in which the histologic examination did not yet reveal the typical granulation tissues. However, the authors cite one case of generalized Hodgkin's disease in which Gordon's test was made on one lymph node that showed the histologic aspects of the disease and on one lymph node that merely showed signs of hyperplasia. The hyperplastic lymph node gave a negative reaction in Gordon's test. The authors admit that this one case does not permit generalizing conclusions but suggest that it shows that a definite diagnosis cannot be based on the outcome of Gordon's test, which is made on peripheral, still unchanged lymph nodes, when the disease is restricted to mediastinal or abdominal lymph nodes. For practical purposes the authors advise the use of half an extirpated lymph node for the histologic examination and preparation of the other half for Gordon's rabbit test, which is to be made if the histologic examination should prove negative.

Endemic of Weil's Disease.—Ehler reports observations in the course of an endemic of Weil's disease, which occurred in a community of Czechoslovakia between March and October. Nearly all the patients (twenty-nine) were children of school

age; two of the patients were adults, namely the teacher in the school attended by the children and his visitor. Search for the source of the infection disclosed that the water of the school well must have been responsible for the infections. Signs of infestation with rats were detected around the well as well as on a nearby creek, the polluted water of which probably entered the well by way of an overflow pipe at times when the water level of the creek was high. In eight of the patients who had severe jaundice it was possible to make serologic tests and in all these agglutination with Weil's *Leptospira* gave positive results, whereas agglutination tests with other organisms, such as typhoid or paratyphoid, gave negative results. The complement fixation with *Leptospira* for the demonstration of antibodies likewise produced positive results in all cases. Following remarks about the symptomatology and epidemiology of Weil's disease, the author says that, whenever cases of severe jaundice occur in numbers, Weil's disease should be thought of and a search should be made for *Leptospira icterohaemorrhagiae*. If this organism is discovered, measures can be taken to prevent additional cases.

Arteries of Kidneys During Hydronephrosis.—Egger describes the morphologic changes which the arterial system of the human kidney undergoes during hydronephrotic degeneration. He also makes an effort to explain how the circulatory conditions during hydronephrosis act on the function of the kidney. He shows that retention of urine may impair the renal function in that by dilating the calices it strangulates the interlobar arteries and thus produces an ischemia in the renal parenchyma. In the same manner the retention produces an obstruction in the interlobar veins and thus a venous stasis results in the kidneys. Ischemia and venous stasis together with the pressure of the retained urine produce an atrophy of the renal tissues. If the stasis of hydronephrosis is relieved in a cautious manner there is the possibility that the parenchyma which is not yet destroyed will recover, for the increasing blood perfusion may promote a functional and even a partial anatomic restoration of the renal tissues. A too sudden relieving of the hydronephrosis may be followed by a further impairment of the renal function. This is probably due to acute circulatory disturbances, which in turn are produced when large quantities of blood enter a diseased arterial system under high pressure. Neural reflexes may also play a part.

Indications for Surgery on Sympathetic Nervous System. W. F. Suermondt.—p. 3443.

Heredity of Epilepsy.—Frets reports the clinical history of a woman, aged 34, who had had epileptic attacks since her fourteenth year. It was found that a nephew of the woman, as well as an uncle, an aunt and a great aunt, all of them relatives of the father, likewise had epilepsy. Thus it seems that epilepsy was hereditary in the father's family. When recessive heredity is assumed, the mendelian law makes it necessary to assume the presence of the hereditary factor for epilepsy in the mother as well. The hereditary factor for epilepsy may be present without there being evident cases of it in the family. The author further reviews the results of recent investigations on the heredity of epilepsy. He cites Rüdin, van Londen, Luxemburger, Conrad, Franke and others, and he shows that the figures on the heredity of epilepsy are much lower than are those on the heredity of dementia praecox. He emphasizes that the etiology and heredity of epilepsy require further investigation.

THE TRAINING OF THE GASTRO- ENTEROLOGIC INTERNIST

CHAIRMAN'S ADDRESS

H. L. BOCKUS, M.D.

Professor of Gastro-Enterology, University of Pennsylvania
Graduate School of Medicine

PHILADELPHIA

The United States of America is now one of the leading medical centers of the world. Let us not forget in the midst of heated criticisms of present day medical care that we are not the backward child but are the advance guard of efficiency and service in the medical art of the world. The high standards of medical education and practice in this country are due in a large measure to the leadership of the American Medical Association. Advances in medicine during the last half century have been so great that specialization was inevitable. This development has not been an unmixed blessing. Unfortunately, some physicians set themselves up as specialists without sufficient training, and it soon became apparent that a plan for the certification of properly trained clinical specialists was needed. The ophthalmologists were the first to establish a board for the examination and certification of physicians qualified by training and experience to practice that specialty. Now, every major branch of clinical medicine has organized similar boards, and the advantages of this movement are recognized almost universally. Meeker¹ recently stated that the organization of the American Board of Surgery in 1937, the last group of specialists to organize in this way, marks the completion of the first stage of a new epoch in American medicine. He further pointed out that the second stage of this evolutionary process obviously must be the setting up of educational machinery fitted to qualify younger physicians for certification by one of the special boards.

It is not my purpose to describe the various methods which may be used by the gastro-enterologic neophyte in order that he may qualify as a specialist. I prefer to discuss not the means of achieving expertness but rather what expertness in the field implies. How should the gastro-enterologist be equipped mentally? What experience must he possess in order to be qualified as an expert? It soon should become obvious even to the beginner that training in the broad field of clinical medicine is essential. The digestive tract may fre-

quently and initially reflect a functional or pathologic disturbance of any major system of the body. The beginner must realize that gastro-enterology can be entered only through the foyer of internal medicine. There can be no short cut. The use of the term gastro-enterologic internist rather than gastro-enterologist will serve to keep this ever in mind. Therefore our candidate first of all should obtain basic training in internal medicine by one of the many plans which are available. Musser² mentioned five: (1) university fellowship, (2) clinic fellowship, (3) hospital residency, (4) preceptorship and (5) formal graduate training. He emphasized wisely, I believe, the assistantship to a reputable internist as a plan which should be open to many and should result in a most satisfactory type of training—if the selection of a preceptor is a wise one. I feel that formal graduate training properly organized by one of the large universities, supplemented by a fellowship, residency or preceptorship, will become the method of preference. No matter which plan is employed, the objective must be sufficient training in internal medicine to meet the requirements for certification by the American Board. Unfortunately, experience in internal medicine does not sufficiently qualify the physician for the special field of gastro-enterology. Advances in the various phases of internal medicine have been so rapid and so extensive that it is no longer possible for the general internist to remain expert in all its subdivisions. Confirmation of this opinion may be found in the personnel of medical departments of most of the leading medical schools. The heads of the departments have associated with them a group of men specially trained in the various subdivisions of medicine. Further proof may be obtained by consulting the current medical literature. Recent advances in our clinical knowledge of any branch of internal medicine emanate usually from workers who are devoting their major efforts to a special field. Gastro-enterology is of wider scope and requires a longer period of apprenticeship than any other subdivision of medicine.

EQUIPMENT OF GASTRO-ENTEROLOGIC INTERNIST

With this brief introduction I will review the mental equipment which the future gastro-enterologic internist should possess. His training should be sufficiently comprehensive so that he may be considered to have a working knowledge of (1) clinical gastro-enterology, (2) neuropsychiatry, (3) endocrinology, (4) allergy, (5) nutrition, (6) physiologic chemistry of the digestive tract and other clinical laboratory procedures, (7) diagnostic roentgenology of the digestive tract and

(8) certain endoscopic examinations. The first five topics are divisions of internal medicine, and basic training in each of them will be acquired during the period of preparation for certification in internal medicine. I shall briefly discuss them separately in order to stress their importance to the gastro-enterologic student.

1. *Clinical Gastro-Enterology*.—Our candidate must acquire a mastery of the symptoms and signs of all functional and organic disturbances of the digestive tract and its appendages. An intimate daily contact with the various manifestations of acute and chronic disorders under the tutelage of an expert will be necessary. Intelligent history taking assumes a place of major importance in this field. This is the starting point in every case study and if not intelligently carried out may lead one far afield. It is obvious that a good history can be taken only by some one who understands the mechanism of the production of subjective complaints and the manner in which they may be modified by the degree of sensitivity of the patient and his emotional reactions to stimuli. The importance of a good history is further stressed by the fact that abnormalities on physical examination are frequently absent in functional and organic disorders of the digestive tract. Finally, the character of the diagnostic studies in any given case depends entirely on data obtained by the anamnesis and physical examination. When the student physician has acquired the training necessary to the taking of a good history and to its intelligent interpretation, he will be on the right road to expertness in clinical gastro-enterology. Naturally, the manner of eliciting and the interpretation to be placed on the various physical manifestations will be part of the equipment of every internist. It always must be borne in mind that symptoms referable to the gastro-intestinal tract are commonly initiated by disorders in other systems, and the gastro-enterologic internist will see many patients whose primary disturbance is not in the digestive tract. It becomes obvious then that he must be primarily a diagnostician of ability.

2. *Neuropsychiatry*.—Few internists can hope to become expert neuropsychiatrists except by neglecting some other phase of their specialty. This is particularly true of the gastro-enterologist whose training requirements are already so comprehensive. However, he, more than any other type of internist, needs a good groundwork in this subject. The relationship between disturbances of the vegetative nervous system and the psyche frequently contribute puzzling problems for solution. The effect of the emotions on digestion has been proved many times since the pioneer work of Pavlov and Cannon, and clinical examples of somatic disturbances of emotional origin are commonplace. Furthermore, many clinicians consider certain organic diseases of the digestive tract like peptic ulcer and ulcerative colitis to be initiated by, or at least conditioned by, emotional states.

Many patients with a psychoneurosis or neurosis consult the gastrointestinal internist because of conversion phenomena or associated functional disturbances. They must be recognized and disposed of intelligently. Probably the strongest argument for psychiatric training is that it causes one to see the patient as an individual rather than as a case. The psychobiologic makeup of a patient will determine his

reaction to any given disease and may modify materially the response of any plan of therapy which may be applied.

This brings us to a brief mention of the art of medicine. The physician or the psychiatrist who does not acquire this elusive faculty, if indeed it can be acquired, is better suited to research and the laboratory. Without underestimating the importance of research and laboratory training, I cannot refrain from admonishing the prospective internist that such training cannot supplant the clinical bedside and office practice apprenticeship which is essential to expertness in clinical medicine. Some men without this clinical apprenticeship occupy major teaching chairs in our medical schools. Their reputations were established by scientific contributions from the research laboratory. A reputation for ability in research does not imply expertness in clinical practice or fitness for teaching. One of the frequent criticisms made of undergraduate medical training is the lack of adequate instruction in the diagnosis and treatment of functional disorders, which are so numerous. The lack of this type of training in many medical schools is apparent to any one seeing large numbers of graduate students from all parts of the country and it is for this reason that I stress its importance to the prospective gastro-enterologist. William J. Mayo,³ in making a comparison between medical education in his day and in 1927, remarked: "Teachers in the older schools were proud to practice medicine. They counted wisdom, that is, the application of knowledge, as being of greater importance than the mere accumulation of knowledge. Today medical researches designed to relieve generations yet unborn are looked on as being almost holy in conception, whereas the relief of people who are now miserable and suffering is too often looked on as rather sordid and commercial." He quotes an old Persian proverb: "He who learns and learns and yet does not what he knows, is one who plows and plows yet never sows." Dr. Mayo's aphorisms apply to 1938 as well as to 1927. Research and clinical medicine are equally important and mutually dependent on each other, but one lifetime is hardly sufficient for expertness in both fields. The clinician should and can carry on research in clinical medicine and the laboratory research worker may to advantage keep abreast of developments in medical practice. However, if the clinician dabbles in laboratory research or the laboratory research worker in clinical medicine per se the results often are not illuminating. A liaison between the two is ideal and usually productive of noteworthy results. The beginner in medicine should choose the field to which he is most suited and train himself accordingly.

3. *Endocrinology*.—Although there is a certain degree of autonomy in gastrointestinal function, the endocrine glands unquestionably exert an important influence. Their action may be exerted through the blood supply directly or by way of the vegetative nervous system. Although specific proof of this effect is often lacking because of the complexity of the endocrine apparatus, clinical manifestations of alimentary tract dysfunction of endocrine origin are commonly encountered. One need cite only the frequent disturbances related to puberty, menstruation and the climacteric, particularly

3. Mayo, W. J.: Medical Education for the General Practitioner. J. A. M. A. 8:1377 (April 30) 1927.

the latter when artificially induced. The disturbances in gastric secretion and in gastrointestinal motility in hyperactive thyroid states are well known. Hypothyroidism is not infrequently associated with symptoms and signs of a neuromuscular imbalance of the digestive tract. Other well developed endocrinopathies have been accredited with causing aberration in the functioning of the digestive tract, but clinical observations are far in advance of actual experimental proof in many instances.

Evidence is accumulating to suggest that some of the more common gastrointestinal diseases may be directly or indirectly dependent on an endocrine influence. Sandweiss, Saltzstein and Farbman⁴ recently reported that 80 per cent of Mann-Williamson dogs had their peptic ulcers prevented, healed or healing by the use of injections of antuitrin-S, whereas twelve untreated (control) dogs died with typical jejunal ulcers. This work, if substantiated, offers an explanation for the clinical observation of Sandweiss and others that pregnancy has a beneficial effect on peptic ulcer and adds further support to the relationship between the pathogenesis of peptic ulcer and endocrine function. I have noted patients in a quiescent stage of ulcerative colitis go into a relapse during pregnancy, and the frequent development of cholelithiasis following pregnancy may depend on a disturbance of bile chemistry, brought about by some hormonal influence.

There are many reasons to feel that endocrinology, a dubious child in the family of internal medicine, may mature into the most influential member of the family, by offering the solution to the pathogenesis of many gastrointestinal and other disorders. Future clinical research in gastro-enterology will unquestionably lead more and more into the field of endocrinology. Surely sufficient reasons have been advanced to stress the importance of securing a basic knowledge of endocrinology.

4. *Allergy*.—The laboratory and clinical training of the gastro-enterologic internist must result in a familiarity with immunology and allergy. Not only does allergy initiate many gastrointestinal disorders but it conditions and complicates many others. A failure to give due attention to the telltale family history, the food idiosyncrasies, the existence of a concomitant allergic state, the eosinophilia, and the effect of vaccines and serums will at times result in an erroneous diagnosis and therapeutic failure. A woman giving an atypical ulcer history, subject to attacks of hay fever and asthma, was recently admitted to the Graduate Hospital with practically complete pyloric obstruction. The stomach was tremendously dilated and retained a large part of the barium sulfate meal for twenty-four hours. A marked eosinophilia suggested an active allergic state. A diet restricted to milk resulted in quick relief and a normally emptying stomach in two weeks. The very rapid disappearance of the obstruction and of the eosinophilia suggested that the allergic factor was of paramount importance. This was substantiated by subsequent study. There can be no doubt of the significance of allergy as a conditioning if not an initiating influence in many patients with the "irritable" colon,

ulcerative colitis and peptic ulcer. No one with clinical experience will deny that our candidate must be at least an amateur allergist.

5. *Nutrition*.—Diet, always an important aid in the therapy of disorders of the digestive tract, becomes more and more valuable as our knowledge of nutrition grows. Its scientific application is of the greatest importance to the gastro-enterologic internist. Primary nutritional disturbances are not rare; their coexistence as complicating influences in many diseases of the alimentary tract is commonly observed. Deficiencies in vitamins, minerals, electrolytes and proteins, singly and in various combinations, render the functioning of the digestive tract abnormal. Conversely, obstructive and inflammatory lesions of the tract are frequently responsible for faults in the ingestion, absorption and utilization of elements essential to health and directly account for deficiencies of various types. The contributions of Minot, Castle, Strauss and others have placed an entirely new interpretation on the anemias, in proving their direct relationship to an aberration of function of the gastrointestinal tract. The accumulated evidence of the interrelationship between the functions of the liver, spleen, bone marrow and digestive tract makes it necessary for the gastro-enterologist to be well grounded in hematology. The science of nutrition is a fruitful field for investigation for the young physician. The portals have just been opened and one of the weakest links in our knowledge of nutrition is its correlation with function of the digestive tract. The gastro-enterologist should be better equipped to fill in this gap than any other type of internist.

6. *Physiologic Chemistry and Other Clinical Laboratory Procedures*.—Gastro-enterology makes greater demands on the chemical and clinical laboratories than any other specialty. The alimentary tract and its complementary organs comprise the important chemical laboratory of the body, so that a thorough training in chemistry constitutes a splendid background for the gastro-enterologist. Such knowledge is essential to an understanding of the physiology of the system and an application of functional tests to the various organs of which it is composed. The functions of the stomach, liver, pancreas and bowel are being subjected to the closest scrutiny and the steady increase in the number of functional tests is constantly augmenting our knowledge of gastrointestinal disturbances. A review of the advances which have occurred in the study of liver function alone since the paper of Rowntree, Hurwitz and Bloomfield⁵ in 1913 would astound the modern Rip Van Winkle in medicine. The progress in this field will be remembered by students of the subject merely by mention of the names of Mann, Bollman, Van den Bergh, Whipple, Rich, McMaster, Elman, Rous, Rosenthal or Bauer. These men have laid the foundations. The building remains to be constructed by the alimentary expert of the future. Our student should not neglect the microscope. He must be familiar with the magnified appearance of sediment contained in the various secretions and excretions. A differential diagnosis may hinge on his qualifications for the recognition of certain pathologic elements. Laboratory training likewise will embrace instruction in the recognition of intestinal parasites.

4. Sandweiss, D. J.; Saltzstein, H. C., and Farbman, Aaron: The prevention or healing of Experimental Peptic Ulcer in Mann-Williamson Dogs with the Anterior Pituitary-like Hormone, *Am. J. Digest. Dis.* 5: 24 (March) 1938.

5. Rowntree, L. G.; Hurwitz, J. H., and Bloomfield, A. L.: *Bull. Johns Hopkins Hosp.* 24: 327, 1913.

7. *Roentgenology*.—The intelligent application of fluoroscopy and roentgenography constitutes the most valuable aid in the diagnosis of motor dysfunction and of organic disease of the alimentary tract. The neophyte will obtain ideal training by associating himself with a roentgenologic expert in gastrointestinal diagnosis who is working in close collaboration with a gastro-enterologist expert in film interpretation. The application of the roentgen diagnosis to clinical problems is the duty of the internist. He alone can muster all the pertinent diagnostic data and should be capable of expert interpretation of the roentgen appearances.

8. *Endoscopy*.—Both ends of the digestive tube can be directly inspected with appropriate instruments. With the introduction of the flexible Wolf-Schindler gastroscope it becomes possible to diagnose more accurately certain diseases of the gastric mucosa. There can be no doubt of the value of this examination in some cases and it should become the most reliable if not the only accurate method of diagnosis of gastritis. However, the instrument has not been used for a sufficient period of time by enough experienced observers to appraise its scope of usefulness. Clinicians are on the threshold of assigning greater clinical importance to chronic gastritis. As gastroscopy becomes more generally adopted, this diagnosis may become even more popular than its importance deserves; but finally it will be assigned to its proper place, and a better understanding of many stomach lesions will undoubtedly result. The gastro-enterologic student should receive training in the use of the gastroscope and be alert to its possibilities, bearing in mind that it is a rather uncomfortable experience for most patients to undergo and consequently that it should be utilized only when definite indications are present.

The lower 10 inches of the intestine can be rather easily inspected with a sigmoidoscope of narrow lumen. Lesions in this region can be diagnosed with certainty by its use. The examination is easily carried out as an office procedure without anesthesia and with very little discomfort. Every patient with symptoms referable to the colon should be subjected to sigmoidoscopy, and every gastro-enterologic internist should be an expert sigmoidoscopist.

SUMMARY

I have attempted to point out that the specialist in disorders of the digestive tract must be first of all an internist. He should obtain the same general training as any other student of internal medicine. In securing this broad training, particular attention should be devoted to neuropsychiatry, endocrinology, allergy and nutrition. He will then be particularly suited to an apprenticeship in clinical gastro-enterology, entailing many special laboratory procedures, diagnostic roentgenography and endoscopy. This is a formidable program. It will be possible of accomplishment for large numbers of physicians when clinical curriculums are arranged by graduate departments of our leading university medical schools. If any physicians are dissuaded from going on it is better so, for it is not a specialty for the weak of heart or the indolent. If others are encouraged to go on I am glad, for they will be of the material from which gastro-enterologists should be made.

250 South Eighteenth Street.

PELLAGRA AND NICOTINIC ACID

R. S. MATTHEWS, M.D.

Assistant Physician, the South Carolina State Hospital
COLUMBIA, S. C.

During the early period of investigation of vitamins Funk demonstrated that nicotinic acid is a constituent of the vitamin B complex. At a later date Elvehjem and his collaborators¹ in their search for the anti-pellagra factor isolated nicotinic acid from highly active concentrates and found that a commercial preparation of this compound was highly effective in curing canine blacktongue. By analogy it was suggested that clinical trials should determine whether nicotinic acid would be equally effective against human pellagra.² More or less recently Spies and Smith and their colleagues, and others³ as well, have demonstrated convincingly the highly effective role of nicotinic acid in the treatment of pellagra. In this section of the United States, where pellagra has often assumed the proportions of a major medical and psychiatric problem, the reports of their work and the results of local experiments produce the impression that a conspicuous advance has been made in the treatment of pellagra.

Since April 30, 1938, sixteen cases of pellagra have been studied in the divisions for white male and female patients at the South Carolina State Hospital. These cases presented various clinical representations of the pellagra syndrome. Fourteen were cases of endemic type and two presented pellagra superimposed on cardiovascular-renal disease. The first six patients to receive nicotinic acid were either considered too ill to permit experimentation with the diet or had been on the traditional treatment for a prolonged period and had failed to recover. During their period of study they received the routine hospital diet without additions, and nicotinic acid. All exhibited prompt improvement and progressed to recovery without interruption. One patient having severe central and peripheral neuritis responded to vitamin B₁ therapy. Four patients, all white women having endemic pellagra, were next admitted and fed a pellagra-producing diet over a preliminary period of observation varying from eight days to one month. Two of these control patients experienced complete remission from pellagra and were paroled at the end of one month, having received no medication and only the control diet. In the other two control cases the condition became progressively worse. Each showed chiefly a marked intensification of the mental and nervous manifestations, one at the end of eight days and the other after twenty-one days. Both patients improved promptly and progressed to recovery when nicotinic acid was administered, the diet remaining unchanged. Six patients were next admitted and placed on the pellagra-producing diet and given nicotinic acid. Three of these patients were severely ill, two having pellagra secondary to a severe cardiovascular-renal condition. One of the two died of heart failure at the end of seven days. Five of the six patients showed

prompt and unequivocal improvement on the control diet plus nicotinic acid from 500 to 1,000 mg. daily, and recovery was completed on a well balanced diet and nicotinic acid.

MATERIALS AND METHODS

A 1 per cent aqueous solution of nicotinic acid was prepared with Merck's nicotinic acid powder; each cubic centimeter contained 10 mg. of the acid. For the purposes of parenteral administration this solution was sterilized and given intramuscularly undiluted or was added to parenteral infusions in quantities up to 100 mg. It was also determined by experience that the sterile 1 per cent aqueous solution could be given intravenously in 10 cc. doses and was well tolerated over a long period of time. For oral administration the nonsterile 1 per cent aqueous solution was given, diluted with a little tap water. The average single dose by mouth was from 100 to 200 mg., or from 10 to 20 cc. of the 1 per cent solution. Nicotinic acid in tablet form supplied by John Wyeth & Brother, Inc., was tried and found to be efficacious. Regardless of the method of administration the desired effects were obtained, but for the sake of economy a solution was prepared in our laboratory as described and easily given then to suit our convenience. The same reactions to the acid that others have described, namely, transitory flushing and tingling or stinging, were observed but in most instances ceased to occur after the patient had been under treatment for several days. The maximum daily amount given was usually 1,000 mg., and in no instance were ill effects of any kind observed other than the transitory flushing and stinging of the skin.

Cases presenting "central neuritis" and peripheral neuritis were treated with synthetic vitamin B₁. For the most part this was given intravenously or intraspinally. The daily dose varied between 10 mg. and 40 mg. In one instance 100 mg. was given intraspinally on three successive days to a very ill patient, and unmistakable improvement followed in both the neurologic and the mental picture.

The control diet used in this study was composed of hominy grits with gravy made from pork fat, corn bread, or wheat bread on days when corn bread was not obtainable, rice, potatoes, molasses, coffee with sugar, and pork fat.

REPORT OF CASES

The following cases are representative of our recent experiences at the South Carolina State Hospital with pellagra, nicotinic acid and synthetic vitamin B₁:

CASE 1.—History.—A. S., a white woman aged 51, a saleswoman and housewife, admitted to the state hospital Jan. 25, 1938, gave a history of a severe attack of pellagra six years previously from which she recovered after nine weeks of treatment. The present illness began in January with anorexia, constipation, pain and weakness in the lower extremities, insomnia and premonition of impending disaster. Two weeks prior to admission, delusions, hallucinations and suicidal tendencies were exhibited.

Examination.—The patient entered the hospital highly excited, disoriented and confused, screaming and clapping her hands continuously. Her weight was 131 pounds (59 Kg.) and her complexion sallow; there was marked dehydration, and the tongue and buccal membranes were scarlet and covered with patches of white exudate. The gum margins were inflamed, and a symmetrical dermatitis with pigmentation and fissuring involved the skin of the dorsum of the forearms, hands and feet. A profuse diarrhea existed. The remainder of the examination was unsatisfactory and revealed nothing essential. The left foot

presented marked talipes equinus, a sequel to a chronic ulcer of the leg six years previously. The hemoglobin content was 63 per cent Sahli, the erythrocyte count was 4,130,000 and the size and appearance of the cells were normal. The total and differential leukocyte counts were normal. The urine contained a trace of albumin, and the blood urea was 60 mg., the creatinine 1.3 mg. The Wassermann reaction of the blood was negative. The rectal temperature was 100.2 F. and followed an irregularly elevated course.

Progress.—It was necessary to restrain the patient in the continuous bath for four weeks. Barbiturates, scopolamine and packs were required at night to combat exhaustion. The routine hospital diet was given by forced feeding. Nausea, gastric distress and rectal pain were complained of. At the end of four weeks, though still in a profound psychotic state, she was quiet enough to permit discontinuance of the bath. For the next two months she received, invariably by forced feeding, a pellagra-preventive diet of high potency, brewers' yeast, liver extract, tablets of vitamin B and G concentrate, tonics and antidiarrheals. At the end of one month of such treatment the dermal and mucosal lesions and diarrhea had disappeared, but dementia persisted as blind confusion and fear, hallucinations, self-accusatory delusions and resistiveness. She suffered extreme anorexia and poor alimentary function. Severe crural neuritis and less severe sciatic neuritis involved both legs. There was intense pain along the course and distribution of the anterior crural nerve and in the flexure of the groin. Intense pain radiated down the inner surface of the leg to the ankles. The extensors of the thigh were weak and the knee jerks were lost. There was pain over the sciatic notch and on deep pressure posteriorly in the muscles of the thigh and calf. The soles of the feet showed hyperesthesia and hyperalgesia, and paresthesias were present in the toes. The right leg was predominantly involved, swollen and pallid from the hip to the toes. The temperature followed a low grade febrile course. At the end of the second month of traditional treatment the patient was bedridden, lay on the right side with the legs flexed at the knees and was fixed in this position by rigid contractures. The size of the right leg had returned to normal. There were slowly granulating decubitus ulcers on each heel. She was exceedingly averse to any change of position. The mental picture was that of resigned inactivity, fear and lack of insight. She frequently responded to hallucinations. Forced feeding was the rule, and the taking of food was obviously an ordeal.

April 20, all the foregoing regimen was discontinued and the patient was placed on the routine hospital diet, without additions, and nicotinic acid. For seven days she received 300 mg. orally and 70 mg. either intravenously in 500 cc. of physiologic solution of sodium chloride or intramuscularly as a sterile 1 per cent aqueous solution. The first significant change occurred on the seventh day, when the patient appeared entirely rational and spontaneously reported an excellent appetite. The temperature had returned to normal. She received thereafter 500 mg. of nicotinic acid by mouth daily and the routine hospital diet. At the end of twenty-one days of nicotinic acid therapy there had been uninterrupted progress to recovery, which appeared complete both mentally and physically with the exception of contractures at the knees, the sequel to peripheral neuritis. The patient remained in the hospital solely for the orthopedic correction of this condition and the old talipes equinus.

CASE 2.—History.—K. S., a white woman aged 29, a housewife, was brought to the hospital May 6, 1938, in a state of incoherent delirium. She had had recurrent pellagra each spring for ten years. Severe mental symptoms had not been observed in previous attacks. The present illness began during the spring of 1938, with general weakness, typical cutaneous lesions on the arms and legs, soreness of the mouth and tongue and obstinate constipation. Because of gastrointestinal symptoms, food had been taken squeamishly. One week prior to hospitalization acute maniacal attacks appeared, with terrifying delusions and hallucinations.

Examination.—The patient entered the hospital delirious and was difficult to manage. On examination she was very ill, emaciated and dehydrated, with typical dermal residuals on the dorsum of the hands and feet and over the elbows. The tongue

was beet red and the tip and edges were smooth. The buccal membranes and pharynx were fiery red and patches of white exudate could be seen. Vaginitis and severe proctitis were present; the patient was menstruating. There were gaseous distention of the abdomen and a severe diarrhea. The rectal temperature was 102.8 F., the pulse rate 130 and the respiratory rate 25. Satisfactory neurologic examination was impossible. The only significant laboratory finding was that of severe anemia, with hemoglobin content 38 per cent Sahli and erythrocytes 2,520,000. Repeated total and differential leukocyte counts were either normal or showed a mild polymorphonuclear leukocytosis. The blood Wassermann test, analysis of a catheterized specimen of urine, blood culture, examination of the stool and of the spinal fluid, blood smears for malaria and x-ray studies of the chest and bony system gave negative results. The estimation of bromide in the blood was 75 mg. The patient was gravely ill for several days and at times appeared moribund. She presented the clinical picture once described as "typhoid pellagra," with continuous high temperature with irregular fluctuations, rigidity of the legs, twitching of the arms, carphology and blind general excitement. The rectal temperature reached 107 F., the pulse becoming at times barely perceptible.

Progress.—Exhaustion was combated by large doses of sedatives; once the patient relaxed only after the intravenous administration of 1 1/4 grains (0.76 Gm.) of sodium amytal with 3/5 grain (0.001 Gm.) of scopolamine subcutaneously. At times the regular hospital diet was taken fairly well by forced feeding; at times it was refused. Repeated administration of fluids and dextrose was necessary for four days. Nicotinic acid therapy was begun the day following admission, 1,000 mg. being given orally in five daily doses, supplemented by the inclusion of 100 mg. in the parenteral infusions. At the end of twenty-four hours glossitis and stomatitis had disappeared and the redness in the pharynx had perceptibly diminished. The oral mucous membranes were clean. On the fourth day the patient began to experience relative mental calm during several hours each day; diarrhea had almost ceased, but high fever and intermittent dementia persisted, with extreme psychomotor excitement at night. On the seventh day of treatment the patient appeared entirely rational and remained thus, the appetite was good and the routine diet was well accepted; the temperature was nearly normal. Proctitis, vaginitis and the other evidences of the pellagrous element, including the dermal residuals, had disappeared, and the patient seemed to be on the road to recovery. Four days later she complained bitterly of pain in the left hip and posteriorly in the left thigh. The temperature rose again to 104 F., and in the course of a few days swelling appeared on the inner surface of the thigh below the flexure of the groin, with intense pain in the muscles and tendons, and posteriorly in the muscles of the thigh and calf, over the sciatic notch and in the popliteal space. The leg was held in flexion, and pitting edema appeared over the tibia, ankle and foot. The knee jerk was hyperactive, ankle clonus was inexhaustible and hyperalgesia and hyperesthesia were present below the knee and over the sole of the foot. The Babinski, Oppenheim and Gordon reflexes were absent. The ankle jerk was absent. Twelve days of continued nicotinic acid therapy, 1,000 mg. daily, did not seem to affect the course of the neuritis or the associated high fever. The patient called constantly for cracked ice, complained of "pain in all her bones," and required large doses of codeine, salicylates and barbiturates. On the twelfth day of this neuritic condition she refused solid foods and was semidelirious with pain. During the next nine days she received daily 12 mg. of thiamin chloride intravenously. Symptomatic relief followed the second dose, and analgesics were no longer necessary. On the ninth day the left leg was essentially normal and the neurologic signs had disappeared. The temperature returned practically to normal for three days and again the patient seemed to be on the road to recovery. Then, in spite of continued vitamin B₁ and nicotinic acid therapy, and a high caloric, high vitamin diet, the temperature rose to 104.2 F., pain began in the right hip, and during the next fifteen days the right leg repeated in all details and with the same neurologic manifestations the course through which the left had passed. The first eight days of this period saw the administration of 12 mg. of thiamin chloride intravenously with moderate amelioration

of the symptoms. Then 10 mg. of thiamin chloride was given intraspinally for seven days. Improvement was strikingly accelerated after the second dose, and at the end of seven days the right leg had returned to normal. Thiamin chloride was continued intramuscularly. The temperature returned to normal three days later and the patient was relieved of all symptoms.

CASE 3.—History.—B. B., a white woman aged 34, a housewife, admitted to the hospital Feb. 15, 1938, gave a history of recurring attacks of pellagra every spring for eleven years, which attacks had become more severe in recent years. The history of the present illness is unreliable but suggests that profound depression preceded or accompanied the appearance of pellagra.

Examination.—When first seen the patient was blindly excited, resistive and totally uncooperative. The limbs showed marked resistance and increased tonus. The general picture, except for its variability, was that of catatonic resistiveness. The arms were held extended above the bed and exhibited subcutaneous tendinosis. Emaciation and dehydration were pronounced; she weighed 99 pounds (45 Kg.). The oral mucous membranes were fiery red, the gums inflamed and bleeding. Salivation was profuse. The skin of the face, neck and dorsum of the hands, forearms and feet showed pigmentation, keratosis and fissuring. The heart tones were rapid; the blood pressure could not be estimated. The rectal temperature was 99 F., pulse rate 100, respiratory rate 20. Constipation was present on admission, followed by profuse diarrhea one week later. Laboratory examinations were not contributory.

Progress.—For ten weeks the patient remained very ill and in a psychotic state throughout. By forced feeding a highly potent pellagra-preventive diet was given, with liver extract parenterally, brewers' yeast and tonics. Antidiarrheals partly controlled diarrhea. Feeding by tube was frequently necessary. At the end of ten weeks the patient lay on her side in bed, with the knees flexed beneath her and the mouth held constantly open, excessive saliva drooling on the pillow. She was unresponsive to verbal stimuli and entirely mute and required every nursing care. Dermatitis and diarrhea had disappeared, but mild glossitis and stomatitis persisted. The gums were foul and several teeth were loose. She had lost 9 pounds (4 Kg.). Urinary and rectal incontinence existed. Forced feeding was necessary. All medicinal and dietary measures were now discontinued and the patient was placed on the routine diet of the hospital. For three days she received 120 mg. of nicotinic acid intramuscularly, and on the third day she began to eat well alone and unassisted. On the fourth day she received 240 mg. intramuscularly; glossitis and stomatitis had disappeared and salivation was almost normal. She was eating well and showed a reviving interest in her surroundings; she left the bed without permission and utilized bathroom privileges for the first time. Thereafter she received 500 mg. daily by mouth and there was a striking return to her normal mental condition by almost successive stages, with progressive disappearance of negativism, disorientation, delusions and faulty insight. At the end of fourteen days of nicotinic acid therapy the patient appeared essentially normal mentally and physically, and four days later, with relief of symptoms, parole was granted.

CASE 4.—History.—Miss L. C., a white woman aged 44, a housekeeper, was admitted to the hospital April 8, 1938, with no previous history of pellagra. The history was unreliable but described the onset of the present illness with weakness, nervousness, loss of appetite, nausea, urinary incontinence, and roughening of the skin of the dorsum of the feet, hands and forearms. She became resistive and assaultive prior to admission.

Examination.—The patient entered the hospital in an extremely dull and apathetic condition, totally disoriented, confused and uncooperative. She was emaciated and dehydrated and weighed 85 pounds (38.6 Kg.). The mucous membranes of the mouth were intensely red and the lips fissured. A bilaterally symmetrical erythema with beginning keratosis involved the skin of the dorsum of the hands and feet and over the elbows. Severe diarrhea was present. There was a low grade fever. The knee jerks were hyperactive. Laboratory examinations were not significant.

Progress.—For three weeks the mental condition exhibited periods of dulness and apathy alternating with excitement and confusion. An occasional brief interval of apparent lucidity occurred at first. For the first three weeks she received a pellagra-preventive diet of high potency, liver extract, brewers' yeast, antidiarrheals and sedatives for excitement. The diarrhea ceased and food and medicine were taken fairly well, but the cutaneous lesions and dementia persisted. The patient lay in bed in a state of settled gloom, with total disregard for her surroundings. Progress seemed to be at a standstill. April 30 the special diet and medicines were discontinued and the patient received the regular hospital diet and 60 mg. of nicotinic acid intramuscularly. Then for fourteen days she received 500 mg. orally and 60 mg. parenterally, with alternation of the intravenous and intramuscular routes. There was a concomitant improvement in the mental and physical condition, with perceptible change almost daily. May 14 the patient was ambulatory, entirely lucid, cheerful and eager to return home. Appetite and digestion were excellent and she had gained several pounds. The cutaneous lesions receded during the first week of nicotinic acid therapy. Parole was granted with relief of symptoms May 23.

CASE 5.—History.—M. G., a white woman aged 45, a housekeeper, admitted to the hospital April 29, 1938, had had recurrent pellagra for several years. During the past three or four years pellagra had recurred each spring with weakness, anorexia, typical symmetrical dermatitis, sore mouth, alternating constipation and diarrhea, and unsteadiness in the legs. The present attack began shortly after Christmas 1937 with generalized weakness, loss of appetite, constipation, nausea, sore mouth, excessive salivation and reddening, fissuring and bleeding of the skin of the dorsum of the hands and feet. A few days prior to hospitalization self-accusatory delusions developed with nocturnal restlessness and excitement, and it became necessary to bring the patient to the state hospital.

Examination.—On admission the patient was exceedingly irritable and agitated but approximately clear mentally. She was unable to walk or stand unassisted and stated that she had not done so for months. Significant was the fiery red, swollen tongue, with small ulcers on the inferior surface. The gums were inflamed and swollen. The buccal membranes and pharynx were scarlet and ptialism was evident. The skin of the dorsum of the hands and feet was keratotic and fissured. There were gaseous distention and generalized tenderness of the abdomen, and proctitis was present. The patient complained bitterly of nausea. The knee kicks were hyperactive and the muscles of the lower extremities were atrophied and flabby. The soles of the feet showed hyperesthesia and hyperalgesia, but no further neurologic examinations were made. The temperature, pulse and respiration were normal; blood pressure was 100 systolic, 80 diastolic. Laboratory examinations gave negative results.

Progress.—The patient was given the regular hospital diet and for three days received 80 mg. of nicotinic acid by the intramuscular route. Twenty-four hours after the first dose she reported diminution of pain in the mouth, and ptialism had ceased. The oral and pharyngeal membranes had blanched perceptibly. Depression and extreme irritability persisted, and forced feeding was necessary. On the fourth day the dose was changed to 500 mg. orally and 60 mg. intramuscularly. Stomatitis, glossitis and pharyngitis had practically disappeared, the mental attitude was less despondent, and improved appetite was noted. On the seventh day of nicotinic acid therapy the tongue, buccal membranes and pharynx appeared normal, the appetite was good and the mental attitude was cheerful and cooperative. Nicotinic acid was continued by mouth, 500 mg. daily, and on the sixteenth day of treatment the patient was ambulatory, the appetite was voracious, and gastrointestinal function was normal. The dermal lesions of the hands and feet disappeared gradually. Convalescence continued in the hospital for nine days more, and the patient was sent home symptom free.

CASE 6.—History.—E. A., a white woman aged 35, a housekeeper, admitted to the hospital May 7, 1938, gave a history of recurrent pellagra in the spring for the past nine years. The present illness began during the latter part of March with anorexia and loss of weight, soreness of the mouth and tongue, alternating diarrhea and constipation, and the appearance of

the typical rash. Restlessness, suicidal tendencies and intermittent attacks of mental excitement supervened and the patient was brought to the state hospital.

Examination.—On admission the patient was irritable and despondent but otherwise clear mentally. She was quite weak and unsteady and somewhat underweight. The essential physical manifestations were symmetrical, erythematous lesions of the face and neck, and the tip, edges and inferior surface of the tongue were fiery red, smooth and painful. The pharynx was red. The skin of the dorsum of the hands and feet and over the elbows and tibias was leathery and pigmented and the epidermis exfoliating. The gums were inflamed and discharging. The remainder of the examination revealed nothing of significance, and the laboratory examinations were noncontributory with the exception of the estimation of the bromide content of the blood, which was 125 mg.

Progress.—Following admission, the patient received 100 mg. of nicotinic acid intravenously in 500 cc. of physiologic solution of sodium chloride and 500 mg. orally in five doses at hourly intervals. At the end of seven and one-half hours glossitis, stomatitis and swelling of the tongue had perceptibly diminished and the patient reported improved sensation in the mouth. No food had been taken during this time. At the end of twenty-four hours glossitis, stomatitis and pharyngitis had subsided and the mouth was not painful. Constipation and pyrosis persisted but the routine hospital diet was well taken and appetite was obviously improved. Nicotinic acid therapy was continued orally, 500 mg. a day, and at the end of eight days the patient showed relief of all symptoms of a pellagrous nature. The condition of the gums was much improved. There was visible gain of weight and the patient reported that she "stayed hungry." Parole was granted a few days later.

CASE 7.—History.—C. O., a white woman aged 32, a housewife, was a patient in the state hospital in 1929 with pellagra and psychosis, paroled at the end of three months when she had recovered. Three subsequent attacks of pellagra occurred prior to the onset of the present illness, which began in the spring of 1938 with loss of appetite, soreness of the mouth, tongue and vagina, pyrosis and constipation, and the typical red rash on the hands and legs. Two weeks prior to commitment, mental symptoms appeared in the form of terrifying delusions and hallucinations, and the patient became uncontrollable.

Examination.—She was admitted to the hospital May 13, 1938, in an extremely dull and apathetic state. Orientation was approximately correct. On physical examination the patient was weak, emaciated and dehydrated, with brownish pigmentation and branny scaling of the skin of the face, the dorsum of the hands and forearms, and over the elbows. Vaginitis and urethritis were severe. The tip and edges of the tongue were fiery red and smooth, and the patient complained of a burning sensation in the mouth. The abdomen showed generalized tenderness. The gait was unsteady, and the patient described her feet as "wanting to go the wrong way." The knee kicks were hyperactive, pseudoclonus was present and the Babinski, Oppenheim and Gordon reflexes were absent. The abdominal reflexes were absent. The temperature was subnormal and tachycardia was present. Laboratory examinations were not significant.

Progress.—On admission the patient was placed on a control diet of carbohydrates and pork fat and observed for eight days. At the end of this period she exhibited a marked aggravation of the mental symptoms. She was fearful and apprehensive, refused to remain in bed at night, required forced feeding and was disoriented. Her attitude was negativistic. Physical weakness was more marked and coarse muscular tremors were observed. Nicotinic acid was now given orally, 1,000 mg. in five daily doses. The control diet remained unchanged. On the fourth day of this regimen vaginitis, urethritis and glossitis had disappeared. The appetite was improved, the patient was eating well, and she was more alert and responsive. On the fifth day she was well oriented, stated that she felt "just fine," and manifested a reviving interest in her surroundings. At the end of twelve days of this therapy none of the elements of pellagra were present, the nutrition and general strength were improved, and the mental condition was apparently normal. The patient was assisting with the routine care of others. A high calory, high vitamin diet was now substituted for the con-

trol diet, and two weeks later the patient was paroled symptom free and with a gain of 15 pounds (7 Kg.).

CASE 8.—History.—J. K., a white woman aged 27, a housewife, was a patient in the state hospital in 1935, having had pellagra with psychosis. She was paroled at the end of five months, apparently recovered. The history reported recurrent pellagra each spring since the patient was 11 years of age. The present attack began in December 1937 with the typical red rash, gaseous eructations and diarrhea, soreness of the mouth and throat, and loss of appetite. For one month or more prior to admission food had been taken very poorly. The patient became bedridden and two weeks prior to admission she became apprehensive and depressed and manifested insomnia, delusions and auditory and visual hallucinations.

Examination.—At the time of admission, May 11, 1938, the patient was apathetic and unfriendly but exhibited no other inappropriate behavior. She was well oriented and declared that she was not mentally disturbed. The significant physical changes were emaciation, typical pellagrous residuals on the face and extremities, and mild glossitis and vaginitis. The lower part of the abdomen was tender. Hyperactive knee jerks were the only neurologic manifestations. The temperature was 99 F., pulse rate 94 and blood pressure 120 systolic, 80 diastolic. Laboratory examinations revealed only a mild anemia.

Progress.—The patient was given a control diet of carbohydrates and pork fat and was observed for three weeks. At the end of this period the dermal residuals, vaginitis and urethritis had practically vanished but glossitis persisted. Mental symptoms were most manifest and had become progressively worse. There occurred episodes, usually of only a few hours' duration, in which the patient exhibited a rather typical catatonic state; she stood motionless, refused to speak or eat, required forced feeding, and responded to auditory hallucinations. She arose at absurd hours during the night and began sweeping or playing with paper dolls. Burning of the mouth, throat and stomach was reported at times.

She was now given 500 mg. of nicotinic acid daily by mouth, but no additions were made to the control diet. On the second day of this therapy the patient reported an improved appetite, stated that she felt "lots better," and denied recurrence of hallucinations. She assisted for the first time with some of the ward routine. At the end of eight days the patient volunteered that she was feeling fine and wanted to return home. No dermal or mucosal lesions were evident, and the mental condition appeared normal. There had been no evidence of abnormal behavior since the second day of nicotinic acid therapy. At the end of eleven days of this regimen the gain in weight was 11 pounds (5 Kg.). The patient was now given a well balanced diet, and general improvement continued until parole was granted several days later. The total gain was 21 pounds (9.5 Kg.).

CASE 9.—History.—L. V., a white woman aged 49, brought to the hospital by ambulance June 26, 1938, had a history of recurrent attacks of pellagra for eight years. The present illness began in March 1938, with reddening of the ankles and forehead, loss of appetite, constipation, and generalized weakness and nervousness. The gait became staggering and the patient became bedridden. Eggs, milk and brewers' yeast were given and taken well at times. Two weeks prior to admission, severe pain developed in the neck and shoulders with retraction of the head, and coarse, generalized muscular twitchings were observed at times. Mental excitement with delusions and auditory hallucinations, followed by exhaustion and stupor, supervened, and the patient was committed to the state hospital.

Examination.—On admission the patient was negativistic and refused to cooperate with the examiner. It was obvious that she was disoriented and out of touch with her surroundings. Development was good but nutrition was poor and the arms, hands and feet presented typical, keratotic, pellagrous lesions. The tongue was very pale and the papillas were markedly atrophied. Urinary and rectal incontinence existed. Blood pressure was 125 systolic, 90 diastolic. The rectal temperature was 102.4 F., the pulse rate 98 and the respiratory rate 24. On neurologic examination the pupils were found to be equal and regular and reacted to light. The muscles of the upper

and lower extremities exhibited increased tonus and marked resistance to passive movement. Both arms, the right predominantly, were maintained in spastic flexion, and the patient complained bitterly of pain in the shoulders and arms when these parts were manipulated. Bilateral wristdrop and loss of grasp were observed. The biceps, radial and ulnar reflexes were markedly hyperactive, and the act of tapping with a finger over the distribution of the brachial plexus produced pronounced reflex jerks in each arm. In the lower extremities the knee kicks were hyperactive, there was bilateral, sustained ankle and patellar clonus, and the Babinski, Oppenheim, Gordon and Chaddock reflexes were active. Abdominal reflexes were absent. Satisfactory sensory examination was impossible because of the mental condition, but it was ascertained that the patient experienced pain in the hips, thighs and calves, and she volunteered that the hands felt numb and the feet ached "like toothache." She described the feet and legs as feeling "dead and sore." Laboratory examinations were noncontributory.

Progress.—The patient refused to eat following admission and required feeding by tube. At the end of four days her condition remained essentially unaltered. Her diet was replaced by a control diet of carbohydrates and pork fat, which was given by spoon, and she was given 500 mg. of nicotinic acid by mouth daily and received intraspinally 40 mg. of synthetic vitamin B₁ for nine days. On the second day of this therapy it was observed that the patient was eating the control diet well, and she reported an improved appetite. She stated that she felt less general pain and aching, but she remained disoriented, stuporous at times and without insight. The neurologic status was examined daily, and at the end of forty-eight hours there were less pain and less spasticity in the extremities, and hyperexcitability of the normal reflexes was perhaps diminished. She was decidedly more cooperative. Improvement was gradual but progressive in all fields, and on the ninth day the patient was well oriented, pleasant and cooperative. She exhibited urinary and rectal incontinence no longer, her appetite was good, and she took the control diet well and requested still more. She was eating unassisted. Moderate hypertonus and pain persisted in the upper extremities with hyperactive reflexes, but wrist drop had disappeared and the hand grasp was much stronger. The only significant reflexes elicited with certainty in the lower extremities were ankle and patellar clonus and a suggestive Babinski reflex. The temperature was normal after having attained a maximum of 105 F. on the third day. Memory and concentration were still poor and insight was only partial, but the patient was much brighter and more comfortable. She was now given a well balanced diet, supplemented by 500 mg. of nicotinic acid orally and 40 mg. of thiamin chloride intravenously. General improvement continued, and at the end of another nine days the patient was mentally clear, cheerful and friendly and insisted on walking a few steps with assistance. At the time of this report the only objective neurologic manifestations are sustained ankle clonus and unsteady gait when walking is attempted. Subjectively the patient experiences slight soreness in the calves and hypoaesthesia of the soles. Her general strength and nutrition have strikingly improved and she is apparently approaching recovery.

COMMENT

In none of the cases studied were gastric analyses performed, nor was the urine examined for excretion of porphyrin, these laboratory procedures not being available at the time of this study.

An interesting observation was the lack of recurrence of pellagrous dermatitis in several of these pellagrins when exposed repeatedly to the direct rays of intense sunlight during the period of nicotinic acid therapy for as long as forty minutes at a time.

SUMMARY AND CONCLUSIONS

1. Thirteen classic cases of endemic pellagra responded promptly to nicotinic acid therapy. The most striking as well as the most gratifying observations in my experience were the rapid healing of lesions in the alimentary

tract with development of an excellent appetite and gastrointestinal function, and the spectacular disappearance of mental symptoms, which in several cases were profound and of protracted duration.

2. Of four control patients on a pellagra-producing diet without medication, two who were not severely ill underwent spontaneous remission from pellagra, while two became progressively worse, showing marked exacerbation of the mental and nervous symptoms chiefly. The latter two recovered dramatically when the control diet was supplemented with nicotinic acid.

3. Five cases of pellagra, four endemic and one secondary to cardiovascular-renal disease, showed marked improvement or actual remission of the pellagrous element when given a pellagra-producing diet and nicotinic acid.

4. In a case of pellagra secondary to cardiovascular-renal disease terminating in heart failure, blanching of erythema of the face and neck and over the sternum on the second day of nicotinic acid therapy was observed. The same effect was observed in other cases. In a case presenting erythema of the entire face, with dilatation and plugging of the sebaceous follicles of the nose and deep redness and leathery induration of the skin of the neck, nicotinic acid therapy produced blanching within forty-eight hours and a return to normal color and condition in the course of a few days. During this time the patient was receiving a pellagra-producing diet.

5. Nicotinic acid does not seem to be therapeutically effective against the peripheral neuritis associated with pellagra, nor does it seem to influence directly the condition described as "central neuritis." Synthetic vitamin B₁ given intravenously and intraspinally in large doses produced prompt amelioration of symptoms and rapid improvement in these conditions.

6. Nicotinic acid has already proved to be not only a medical boon but an economic blessing to a large state institution where pellagra has often constituted a serious problem. The period of hospitalization (to say nothing of the mortality rate) for the usually severe type of case which is received here promises to become vastly reduced, while the actual cost of the nicotinic acid as given has been relatively negligible in the individual case.

All Calcium Replaced Every Six Years.—Calcium is the most permanent thing in animal life. The chalk cliffs of Dover, so dear to the English heart, are made up of the calcium compounds of the mollusk shells and urchin spines which dropped to the ocean bed a hundred million years ago. Large animal bones and teeth have remained in protected places almost intact for millions of years, and the only evidence we have of man's first million years is in the calcium-bearing bones and teeth which he has left. These bits of us which may survive for posterity amount to but little more than a box of chalk, but to maintain this meager storehouse the average adult must assimilate about 0.45 gram (0.016 ounce) of the element calcium per day, for the bones and teeth are continuously breaking down and exchanging new molecules for old, and calcium is being continuously excreted. All of our calcium is completely replaced about every six years, and the only way to maintain the balance in the body is to take in a sufficient quantity in the food. If there is insufficient intake the body tries to make adjustment, but it is never completely successful. It goes on excreting calcium, taking it from the bones and teeth. If calcium deficiency continues for long periods, the attempted adjustment evidences itself in serious ill health of various sorts, and if the shortage is really severe, premature death is almost certain.—Furnas, C. C., and Furnas, S. M.: *Man, Bread and Destiny*, New York, Reynal & Hitchcock, 1937.

PREGNANCY AND TUBERCULOSIS

JANE SKILLEN, M.D.

AND

EMIL BOGEN, M.D.

OLIVE VIEW, CALIF.

The relationship between pregnancy and tuberculosis has been a topic of interest to physicians and their patients for centuries. In the old writings one finds repeated expression of the notion that sterility may be a factor in the pathogenesis of consumption. Pregnancy was prescribed, therefore, for its prevention or treatment. "Among those who have entertained the opinion that pregnancy impedes the march of phthisis may be mentioned Rokitsansky, Clark, Williams, Andral, Warren, and, indeed a large majority of observers, up to the close of the last century."¹

The converse doctrine that conception, pregnancy, parturition and lactation, together or singly, once or repeated, may be responsible for the breakdown was later asserted. Grisolle maintained that "pregnancy manifests a marked injurious influence over the progress of phthisis while accouchement and the puerperal state

fail to exert any prejudicial influence over the march of the pulmonary disease; but, on the contrary, the disease goes on as before, uninfluenced by the puerperal state, or in the less intense cases, it is more or less perfectly arrested."

Most other writers reversed these conclusions and insisted that it was particularly parturition and the puerperium that were to be feared. Continence, sterilization, contraception or abortion were, accordingly, enjoined on the women subject to the infection.² The maxim that "a tuberculous maiden should not marry; a tuberculous wife should not conceive; a tuberculous pregnant woman should not carry through" was widely quoted.

The few reports obtainable of experiments on the effect of pregnancy on tuberculosis in animals show little connection between these conditions. Several workers observed a slight retardation of tuberculosis in small groups of guinea pigs which had been allowed to become pregnant.³ A group of 140 pregnant tuberculous animals studied at Olive View, Calif., showed just about the same average amount of disease as the

controls. The injection of follicle-stimulating and of estrogenic substances and of corpus luteum extracts also failed to influence the course of the disease in our animals. No significant difference in the resistance to tuberculosis could be shown between guinea pigs of different sex or ages.

It has been repeatedly stated that tuberculous women may enjoy a temporary remission of the disease during pregnancy, only to relapse with increased activity after parturition.⁴ When divided according to the stage of pregnancy in which infection occurred, however, guinea pigs infected late in pregnancy generally showed no more tuberculosis than those inoculated earlier.

If the raised diaphragm, analogous to that produced by pneumoperitoneum, had a beneficial effect by producing pulmonary collapse, it would be expected that this effect would be manifested particularly in animals infected by inhalation and not in those with abdominal infection from subcutaneous injection.⁵ In our experiments no such difference was observed.

If the drainage of the mother's system by lactation was the important factor, as has been suggested, removing the young at birth should have a beneficial effect and wet nursing an ill effect.⁶ Experimentally, tuberculous guinea pigs given excess progeny to nurse showed a slightly higher mortality rate, but the extent of the tuberculous lesions observed in these animals was no greater than that in the controls or in those whose young were removed.

The fact that the rate of death from tuberculosis is higher for young women between the ages of 15 and

30 than for other females or for young men of the same ages has been ascribed in part to increased susceptibility resulting from pregnancy.⁷ Study of vital statistics indicates that the difference is not constant, being marked years before pregnancies may be expected to occur but disappearing when the child-bearing period is only half completed.⁸ Analysis of the records of death from tuberculosis reveals rather an infrequency of pregnancies in the group involved.⁹ More intensive study of the subjects concerned shows an incidence of intimate contact and massive exposure, as in the case of a nurse or personal attendant on a consumptive, which may account for the difference.

The effect of pregnancy on the course of tuberculosis may be estimated from three types of data available at Olive View; namely, the extent of tuberculosis found at admission in patients with various pregnancy histories, the response to treatment of patients who became pregnant while in the sanatorium, and the effect on the future life expectancy of those who become pregnant after leaving the institution.

The records of 10,000 patients admitted to the Olive View Sanatorium were examined. Half of these were males (4,875), and nearly half of the remainder (5,125) single women (2,492), leaving 2,633 married women, of whom 500 had never become pregnant according to their histories and 718 had never borne a living child. Of the women with a history of pregnancy, more than a third reported only one child, and the average number of children per woman was only 2.2, although many more pregnancies were recorded. The average length of time at admission since the last pregnancy had occurred was about five years. Since the average duration of married life was only nine years, with 2.4 pregnancies per woman, the average interval between a pregnancy and any chance event would have been even less. The pregnancies were therefore not significantly related to the incidence of the tuberculosis.

Analysis of the stage of the disease in single, childless and parous women shows little difference in the extent of the disease on admission. The end results or case fatality rates give similar figures.

About fifty women were pregnant at the time of admission to the sanatorium or became pregnant while away from the institution on a pass. For ten of the fifteen who were away, the date of probable exposure to conception and the date of the last menstrual period were known. Exposure in all cases took place between twelve and eighteen days before the next period, approximating the so-called fertile period, or time of ovulation, according to Hartman¹⁰ and others. For the prevention of such conceptions, if it is desired to lessen them, it has been suggested that patients be given passes home only during the week before and the week after onset of the menses. One patient, however, who claimed to have followed this rule faithfully, nevertheless became pregnant after discharge. Contraceptive advice and equipment was given to many of these women and to other women when they went out on passes or on discharge, though not uniformly. One pregnancy was reported in spite of assertedly conscientious use of a contraceptive powder without an occlusive diaphragm or pessary.

Of the fifty women, fourteen were allowed to be delivered while most of the others had a therapeutic abortion, performed either vaginally or by abdominal hysterotomy, usually accompanied by sterilization. The stage of the tuberculosis and the fate of these women according to the treatment given are here of interest.

As might have been expected from the general distribution of admissions to Olive View, only three of these women had minimal tuberculosis at the time of admission, and these three were alive when last heard from. Eleven had moderately advanced tuberculosis; of these only one has since died (soon after abortion was performed). Thirty-six had far advanced tuberculosis; sixteen are known to have died, six after full term delivery and ten after abortion, with an annual case fatality rate of 8 per cent a year for those delivered at term and 7 per cent for those whose pregnancy was aborted. The mortality for those delivered at full term is little higher than the rate for those whose pregnancy was aborted, and neither rate seems higher than that of the general sanatorium population.

Responses received from patients discharged from Olive View indicate that more than fifty other patients became pregnant after leaving the institution and that most of them went on to term. The mortality rate in this group was extremely low; only two of the patients are now known to be dead, and both were in the group of ten with far advanced tuberculosis when admitted. It is obvious, however, that the patients who responded to inquiries might have been expected to have a better fate than the remainder, since they lived at least long enough to send us the information and probably considered themselves in good enough shape to enter into pregnancy.

Despite our negative statistics many of the 2,633 female patients, as well as the physicians interviewing

true, they deserve much weight. It may be questioned, however, whether they more than express the prejudices or preconceptions of the patient or those of the examining physicians, often made known in an accompanying note. The greater attention given a woman's health during pregnancy may be a factor in revealing otherwise overlooked conditions.

* Five, thoracoplasty.

The direct physiologic effect of pregnancy, parturition and lactation may actually represent a minor aspect of the real problem. One of the most important factors in the treatment of pulmonary tuberculosis is rest. It is almost impossible to induce many mothers to take the amount of rest required for their condition, and particularly to leave their children and go to a sanatorium for the treatment they require. Other therapeutic factors are also closely linked with the economic situation of the patient. If the added expense of bearing and caring for a child means that the mother will be deprived of adequate food, rest and medical care, it cannot be lightly incurred. Adequate economic aid, however, may often safeguard the mother even better than interference with pregnancy.

The treatment of tuberculosis in a pregnant woman should not be interrupted by the pregnancy. Pregnancy proceeding to successful delivery and recovery while the lung remains collapsed under artificial pneumothorax, phrenic interruption or even thoracoplasty is by no means unusual today. A recurrence developed after delivery in only a few of the twenty cases observed at Olive View.

CONCLUSIONS

By and large, it seems that the tuberculous woman who becomes pregnant has a course not greatly different, so far as her tuberculosis is concerned, than her tuberculous sister who does not become pregnant, while so far as her pregnancy is concerned she does not greatly differ from other pregnant women. The tuberculous woman who becomes pregnant should have the benefit of expert medical attention both for her tuberculosis and for her pregnancy, but the woman who faces only one of these conditions at a time should likewise have expert care. If the pregnant tuberculous woman has active disease she should have active collapse therapy and rest treatment, but so should she if she were not pregnant. A long and exhaustive labor should be avoided for the tuberculous women by the use of obstetric analgesia and surgical intervention when indicated; but this is becoming a general demand.

In cases of well healed, arrested tuberculosis many exertions may be safely undertaken that should be forbidden during a more active phase. In unstable conditions, when the future course of the disease hangs in

them, stated on admission that they traced the breakdown to the last pregnancy. One hundred and twenty-two, or about 5 per cent, stated definitely that the onset of tuberculosis was observed in connection with a pregnancy: during the course of the pregnancy in twenty-six cases, after a miscarriage in twenty-seven and after a delivery in sixty-nine. Several of the letters received after discharge stated that the mother was in poor condition after delivery. If these statements were really

the balance, pregnancy should be at least postponed. Contraceptive measures may sometimes be recommended to a woman with tuberculosis in whom, if pregnancy does occur, it may be allowed to proceed without interruption. With extensive advancing lesions and with greatly diminished respiratory reserve, on the other hand, every precaution must be taken to avoid overtaxing the patient's strength. Since the seriousness of the obstetric complications increases with delay if abortion is performed, early diagnosis by means of biologic tests should be made. Interruption may then be done with the least possible trauma and risk. The occurrence of pregnancy should not allow neglect of the pulmonary condition before, during and after the obstetric management.

ABSTRACT OF DISCUSSION

DR. J. C. IRWIN, Los Angeles: This paper opens the way for a discussion of one of the most important problems that confront the obstetrician and phthisiologist. It has been estimated that 30,000 tuberculous women become pregnant in this country annually and that a third, or 10,000, of them die within a year after delivery. With such an appalling death rate it is hard to reconcile the statement that the tuberculous woman who becomes pregnant has a course not greatly different so far as her tuberculosis is concerned from her sister who does not become pregnant. This group of 30,000 cases does not include many thousands of cases of incipient disease which are never recognized and in which recovery occurs. About fifty years ago it was believed by a considerable number of clinicians that pregnancy improved tuberculosis. In fact, the young tuberculous woman was advised to marry. Following that period the pendulum swung to the other extreme for twenty-five years, when probably a majority of clinicians advised therapeutic abortion in practically all tuberculous women so diagnosed in the first half of pregnancy. During that period I formed a lasting opinion, as one is prone to do in the early years of clinical training and experience. As a resident and instructor at the University of Pittsburgh, I had charge of 3,000 deliveries in the home. Of these, nine women died of tuberculosis within the first three months post partum. None died before delivery. That lasting impression is that, in spite of experimental data on animals, pregnancy does constitute a serious drain on the tuberculous mother. The fact that she gains weight and looks better during pregnancy is misleading to the clinician and constitutes one of the most puzzling phenomena in clinical medicine. There is something that carries the chronically ill and doomed woman through pregnancy until her function with regard to propagation of the species has been fulfilled and then allows her to die, sometimes quickly. Had this phenomenon not been observed in the woman afflicted with cancer, diabetes and pernicious anemia, I would be inclined to believe that in the case of tuberculosis it is due to a gradually increasing partial collapse effect of the pregnant uterus. The rapid invasion of the disease shortly after delivery could certainly be explained by the sudden relief of the pressure allowing the lung to expand. This, then, suggests a definite indication for collapse therapy in the first few hours or days after delivery of the active, tuberculous woman who goes to or near full term pregnancy. Opinion as to proper procedure and treatment, I believe, now lies in the middle course. The improvement in the treatment of pulmonary tuberculosis by surgical means, added to the old rest and fresh air treatment, has changed the picture almost completely. The tuberculous patient who is seen for the first time in early pregnancy should be examined carefully by the phthisiologist for activity, and his advice should be followed after observation of the patient for a short time. I believe that abortion should be performed in active tuberculosis if the patient is seen early when the abortion can be done under evipal or spinal anesthesia.

DR. EMIL BOGEN, Olive View, Calif.: More than one tenth of all the patients in whom tuberculosis is diagnosed die annually. Pregnancy gives no definite protection against this

high mortality rate in tuberculosis. Despite the best efforts of obstetricians, pregnancy itself carries considerable hazard. Tuberculosis offers no insurance against that hazard. The woman who has tuberculosis and pregnancy is in greater danger than the woman who has only one of these conditions, but it is not because of any increased mortality due to either one of the conditions; it is merely the summation of the two forms of risk. Another factor which must be considered in advising a tuberculous woman as to whether she may or should become pregnant is the question of the fate of the child following childbirth. In the past, the outlook for children of tuberculous parents was extremely dismal. At present it can be said that in patients whose tuberculosis has been arrested, and who are continuing under good medical care, the outlook for the children is very good. In instances in which the patient has active disease with positive sputum, separation of the child from the parent is generally advised, and the woman with active tuberculosis who undertakes a pregnancy should look forward to a prolonged separation from her child.

A TEN AND ONE-HALF DAY CHIMPANZEE EMBRYO, "YERKES A"

J. H. ELDER, PH.D.

ORANGE PARK, FLA.

CARL G. HARTMAN, PH.D.

AND

C. H. HEUSER, PH.D.

BALTIMORE

Through the cooperation of the Yale Laboratories of Primate Biology and the Carnegie Laboratory of Embryology, an implanted ovum of the chimpanzee, slightly younger than the earliest human ovum, has been secured. The circumstances leading to this achievement and the similarity of this youngest anthropoid to the human embryo render the occasion of interest to the gynecologist, the embryologist and the anthropologist alike.

The success that attended the enterprise was no mere accident, though a certain amount of good fortune favored us. The time of ovulation was calculated from data collected by the staff of the Yale station over a period of years. At the suggestion of Dr. Robert M. Yerkes, director of the Yale Laboratories, one of us (J. H. E.) set out to determine the relation of ovulation to externally manifest events of the menstrual cycle, namely to the menstrual flow and, more precisely, to the intermenstrual swelling of the sex skin.¹

TIME OF OVULATION IN THE MENSTRUAL CYCLE

Because of the difficulty of handling the sexually mature ape, the method of choice in determining ovulation is that of isolated coitus. Since it is now known for a number of mammalian species that spermatozoa remain effective for fertilization in the female genital tract for a maximum of twenty-four hours and the ovum not more than twelve hours, insemination within the limits of a menstrual cycle served tentatively in the chimpanzee to fix the time of ovulation within a day or so of coitus.

Preliminary to such experiments, however, the menstrual cycle had to be studied in numerous individuals. On the basis of 164 cycles recorded for eleven mature female chimpanzees, it was found that the length of the modal cycle is thirty-five days, or a week longer

1. Elder, J. H.: The Time of Ovulation in Chimpanzees, *Yale J. Biol. & Med.* 10: 347-364 (March) 1938.

than in most other primates with the possible exception of certain baboons and the gorilla.² In common with baboons, certain macaques and other monkeys, the chimpanzee exhibits tremendous swelling of the sex skin during the midinterval. This ordinarily reaches its maximum not later than the fifteenth day of the cycle and remains in this condition for about ten days. The inactive period, including the menstrual flow, is variable, ranging from 5.1 to 13.7 days in the series studied.

Since similar swellings may be produced in juvenile females by injections of estrogen, it is assumed that the genital swelling is conditioned by a growing ovarian follicle. The beginning of detumescence, therefore, may be expected in normal cases to mark the establishment of a corpus luteum following ovulation. In fourteen unequivocal cases, supported by others less exact, Elder¹ learned that ovulation occurred a few days before the sex skin began to regress—usually from one to three but in other cases up to five days. For the present observation, in order to increase the chances of securing a fertilized ovum, two subjects were mated daily for a period of five days prior to the anticipated day of detumescence.

HISTORY OF FERTILE FEMALE

Two attempts have been made thus far to apply the facts ascertained in the isolated coitus procedure to the task of securing a young embryo. In at least one case, that of Mamo, the efforts were crowned with success. The endometrium of a second female (May) has not yet been fully explored. Since this report is concerned chiefly with the specimen obtained from Mamo, we shall present a brief summary of her recent reproductive history.

Mamo has always been an exceptionally healthy and vigorous chimpanzee. On Aug. 14, 1936, she menstruated for the first time at the age of about 8 years. As in adolescent females generally, the cycles of the first year were irregular and probably mostly non-ovulatory. Two cycles of tumescence appeared in April and May 1937 without the occurrence of an intervening menstrual flow. Such anomalous behavior has been noticed also in adolescent rhesus females of the Carnegie Colony.

On days 22, 23 and 24 of the cycle that began Jan. 21, 1938, Mamo was mated with a male of known fertility. On day 24, however, the sex swelling had receded considerably, so operation was deferred for more favorable indications. This proved to be a fortunate decision, for observations on the ovaries a month later showed that ovulation had not taken place during this, the January-February, cycle but probably in the one preceding it, which began Dec. 16, 1937. Mamo again menstruated on February 23.

On each of days 17 to 22 (March 11-16) Mamo again copulated with male Bokar in five minute periods. On day 23 detumescence began and on this day also she refused the male. The ovum to be described, estimated at 10½ days of age, was recovered March 26. This particular day was selected for the operation because an ovum from 10 to 12 days old was desired as a stage approximating the youngest known human ovum. It is gratifying to record the fact that the ovum recovered actually fell within the anticipated range.

ANESTHESIA

Experimental use of various anesthetics in the Yale Laboratories has shown that pentobarbital sodium, alone or supplemented with ether, is a satisfactory agent.³ Tractable animals are trained to receive the drug rectally while presenting the buttocks at the wire netting of the cage. With our present subjects we insured full retention of the solution by giving the injection under initial ether anesthesia, induced by brief confinement in a specially constructed ether chamber. For Mamo, 33 mg. of pentobarbital sodium per kilogram of body weight was given rectally. This had to be supplemented during the operation by small amounts of ether to maintain satisfactory relaxation for laparotomy.

HYSTEROTOMY

The hysterotomy was performed by one of us (C. G. H.), assisted by Dr. Kenneth A. Morris of Jacksonville, Fla. The method for enucleating the endometrium was one that had been worked out and used in nearly 100 operations on the rhesus monkey at the Carnegie Colony, to be described in detail by W. M. Firor. To reduce the hemorrhage the uterine arteries were occluded by means of a rubber tourniquet placed about the uterine isthmus.

The uterus of Mamo, a nullipara, measured 5 cm. in lateral diameter; that of May, a multipara, 6.5 cm. The uterus of the chimpanzee, therefore, approximates that of women in size; but it is more accessible because of the less prominent crest of the pubis in the ape.

After the endometrium was enucleated as completely as possible, the uterus and the abdomen were closed with silk. Subcuticular stitches were used in closing the skin incision, as taught by Dr. Firor for use with animals that cannot readily be handaged. This procedure proved as efficacious in the chimpanzee as in the monkey. Experience with the monkey leads us to anticipate perfect regeneration of the endometrium in the chimpanzee.

The ovaries also were about the size of human glands. In both May and Mamo they were highly vascular. In each animal the right one, containing the corpus luteum, was almost cyanotic because of the numerous veins over the whole surface. The right ovary measured slightly under 20 mm. in Mamo and slightly over 20 mm. in May. In Mamo a small yellow corpus albicans, estimated at more than 1 month old, was present. The ovary of May was removed and will be described together with the endometrium as a whole on another occasion.

THE EMBRYO

In the course of the operation the ventral half of the endometrium was removed first and its surface inspected by the naked eye. Near the midline a tiny hemorrhagic spot like a pinprick was visible, and this was taken as evidence of early pregnancy, since extravasation about the implantation site is characteristic of the primates.⁴ The specimen was immersed in physiologic solution of sodium chloride and within fifteen minutes in Bouin's fluid, in which it was shipped to Baltimore. After fixation it was found that the site of the ovum had become obscured by the opacity of the overlying tissue, but with proper magnification

and illumination it was found again (by C. H. H.). The site was further marked by a tag of coagulum which was determined subsequently to have issued from the site.

The implantation site having been located on the uterine mucosa, it was cut out in a block about 3 by 3 by 3 mm. and was embedded by the double-embedding

surface epithelium, which in places is of endothelial thinness indicative of efforts to heal the wound. In two places the trophoblast seems indeed to be uncovered and exposed to the uterine lumen.

The point of entrance is practically nonexistent and there is no trace of an "operculum" as described for human ova the preservation of which leaves much to

Section 59 of a series of 126 sections (6 microns thick) of chimpanzee ovum "Yerkes A."

method in celloidin and paraffin and cut into sections measuring 6 microns in thickness. The essential features of the embryo can be recognized from the accompanying illustration, which is section 59 of a series of 126 passing through the ovum.

It is seen at once that the ovum is completely buried beneath the surface epithelium, as it is in man at this time, differing in this respect from the shallow attachment in the monkey.⁵ It is situated just beneath the

be desired. In only one limited region (section 4-7, slide 5) is there a definite communication between the ovum and the uterine lumen. It is here that a strand of coagulated exudate containing red blood cells has issued from the site of the ovum. The coagulum is continuous with a lacuna, and blood is present in both.

The trophoblast forms the bulk of the ovum at this stage and is much more developed on the deeper side. On the periphery the plasmoditrophoblast may be seen invading the maternal tissues, sending out diffuse streamers and tapping blood vessels (upper right of illustration). Large lacunae, some containing erythro-

5. Wislocki, G. B., and Streeter, G. L.: On the Placentation of the Macaque (*Macaca mulatta*) from the Time of Implantation Until the Formation of the Definitive Placenta. *Contrib. Embryol.* 27: 1-66 (May) 1938 (publication 496, Carnegie Institution of Washington).

cytes, have formed in the plasmoditrophoblast. The cytotrophoblast lies within this in irregular masses and bounds the segmentation cavity containing a loose reticulum of mesenchyme cells generally designated as extra-embryonic mesoderm.

The embryo proper lies eccentrically. It consists of an embryonic shield with crowded, pseudostratified nuclei and some mitotic figures. It resembles the corresponding stage of the rhesus monkey. The amnion overlies the embryonic shield, from which it is separated by a narrow space, the amniotic cavity. There is as yet no yolk sac and, of course, no gut entoderm. The layer of cells which lies closely applied to the convex ventral surface of the embryonic shield consists of entodermal cells tentatively regarded as primitive and closely related to the other elements of the segmentation cavity, but some of them are destined to form the outer layer of cells bounding the cavity of the yolk sac. This interpretation is based on the embryonic history of the rhesus monkey.

The ovum surrounds a uterine gland with which it happened to come in contact. Where the trophoblast has made contact with the uterine gland, necrosis has resulted; this is especially true of a small isolated portion which has become incorporated into the segmentation cavity.

The following measurements have been made:

Through entire ovum, including outlying streamers of trophoblast: 0.756 by 0.666 by 0.500 mm.

Excluding streamers of trophoblast: 0.720 by 0.600 by 0.500 mm.

Segmentation cavity: 0.333 by 0.213 by 0.200 mm.

Embryo proper: 0.133 by 0.126 by 0.111 mm.

The present specimen is a little smaller and less differentiated than the Miller ovum, the youngest known for man.⁶ The latter measures 0.9 mm. in longest diameter on the slide and possesses a small yolk sac. Streeter estimates the age of the Miller ovum at from 10 to 11 days. On the basis of monkey embryos since collected at the Carnegie Colony, Hartman⁷ has estimated it at 11 days. By comparison the chimpanzee ovum may tentatively be set at 10½ days of age.

SUMMARY

The time of ovulation with reference to the sexual swelling having been determined at the Yale Laboratories of Primate Biology, the Carnegie Laboratory of Embryology cooperated by assisting in the recovery of the ovum surgically and by preparing and studying the unique specimen.

The ovum contains an embryo provided with amnion but no yolk sac. It is one-fourth smaller than the Miller ovum, the youngest human specimen, which possesses a yolk sac. Implantation is "interstitial" as in man. The Miller ovum is estimated at 11 days of age, the chimpanzee ovum at 10½ days. It was recovered on day 32 of the cycle. In association with a thirty-five day menstrual cycle the chimpanzee ovulates about seven days later in the cycle than the rhesus monkey.

HYPERTENSION IN A PATIENT WITH A SOLITARY ISCHEMIC KIDNEY

GUSTAVE FREEMAN, M.D.

AND

GEORGE HARTLEY JR., A.M.

CHICAGO

Goldblatt¹ and others have shown that hypertension develops in dogs and in monkeys when one kidney is made ischemic by partially clamping its artery. The hypertension is more readily produced when one kidney is first removed. This case is reported because of its bearing on previous work and because no analogous case has been found in the literature.

REPORT OF CASE

History.—A man aged 57, who first came to the University of Chicago Clinics July 27, 1937, had pneumonia at the age of 30 but was otherwise well until December 1935, when he fell

Fig. 1.—Section of surgically removed kidney showing normal parenchyma (hematoxylin and eosin stain).

down a flight of stairs. The same day the right kidney was removed because of laceration. Histologic preparations of the removed kidney showed no pathologic changes except massive hemorrhage at the site of laceration (fig. 1). After the operation thrombophlebitis developed in the legs, but otherwise the patient recovered without difficulty.

He was well for sixteen months after the operation. During that time several normal readings of the blood pressure were obtained by the attending physician. In April 1937 he began to have headaches and nausea. Two months later, in June, he visited the physician, who found a systolic blood pressure of 230 mm. There was still occasional swelling of the left leg on standing.

Dr. Isadore Pilot made possible examination of the surgically removed material.

From the Department of Medicine and the Department of Pathology of the University of Chicago.

1. Goldblatt, Harry: Studies on Experimental Hypertension: V. The Pathogenesis of Experimental Hypertension Due to Renal Ischemia, Ann. Int. Med. 11:69 (July) 1937.

In July 1937, when he was first examined at the University of Chicago Clinics, the only abnormal observations were evidence of recent loss of weight, minimal thickening of the retinal arteries and mild compression of the veins by the arteries, a high pitched second sound at the aortic area, a blood pressure of 230 mm. of mercury systolic and 140 diastolic, an indirect inguinal hernia and a ganglion on the right wrist. Bulging of the superficial veins of the left leg could be produced by having the patient stand.

The patient was not admitted to the hospital until September 1. No significant change had taken place except the appearance

Fig. 2.—Atheromatous plaque at orifice of renal artery (indicated by arrow).

of slight retinal edema, a few small hemorrhages in the nerve fiber layer and indications of absorption of previous hemorrhages in the retinas. An increase in disproportion of arteries to veins was also noted. The patient was hospitalized for forty days without improvement. The blood pressure varied from 220/138 to 270/150. Eight examinations of the urine were made. The specific gravity varied from 1.015 to 1.023 without forcing urinary concentration. No albumin or sugar was found. Occasional hyaline casts and leukocytes were seen in centrifuged specimens. Red cells were absent. The white cell count varied from 8,800 to 9,400 per cubic millimeter. The differential count was normal. The red cell count averaged 4,500,000 per cubic millimeter. The hemoglobin content averaged 85 per cent. The stools were not abnormal. The Wassermann and Kahn reactions were negative. September 2 the nonprotein nitrogen content of the blood was 33 mg. per hundred cubic centimeters; the total protein content of the plasma was 6.41 mg. per hundred cubic centimeters; the level of serum chlorides was 99.9 millimols per liter; the serum pH was 7.49, and the carbon dioxide content of the serum was 29 millimols per liter. On the same day the urea nitrogen content of the blood was 25.6 mg. per hundred cubic centimeters and the urea clearance was 19 by the formula $\frac{U}{B} \sqrt{V}$, or 35 per cent of normal. An electrocardiogram September 17 was reported as showing a PR interval of 0.14 second, a QRS complex of 0.08 second, a rate of 74 per minute and a sinus rhythm. The P waves in lead 2 and in lead 3 were slightly notched. The T wave in lead 1 was practically isoelectric. The T waves in lead 2 and lead 3 were inverted. Left axis deviation was present.

After an absence of six weeks, he was readmitted on December 1. He had been growing weaker. Two days prior to this admission he began to have difficulty in voiding and could pass only a small quantity of urine at a time. Except for frequent hiccuping and a blood pressure of 290/170 there were no changes in the physical signs. Catheterization relieved the bladder of 500 cc. of urine. Because of obstruction in the prostatic portion of the urethra a catheter was strapped in place. The obstruction was apparently due to edema of the mucosa and submucosa. The patient lived seventeen days, during which time frank acute cystitis persisted. A moderate amount of albumin was present, and an occasional hyaline and granular cast was found in all specimens of urine. Red cells were rarely present. Many pus cells were consistently found. There was leukocytosis, with

the count ranging from 15,600 to 27,500 cells. The nonprotein nitrogen content of the blood was 62 mg. per hundred cubic centimeters the day before death. Other blood chemistry determinations were not abnormal. The urea clearance was 13 by the formula $\frac{U}{B} \sqrt{V}$, or 22 per cent of normal, December 8. Another electrocardiogram showed progressive myocardial damage with auricular extrasystoles. The blood pressure fell to 110/50 on the last day. Edema of the extremities appeared terminally. Abnormal distention was troublesome during this period. The patient died December 19, two years after the nephrectomy, of myocardial failure.

Necropsy.—The necropsy was performed four hours after death. The body was emaciated, weighed 109 pounds (49 Kg.) and measured 65 inches (165 cm.) in length. The external ears and nail beds were cyanotic. The abdomen was distended. Both feet and ankles and the entire right arm and hand were edematous.

The loops of the small intestine were markedly distended and were dark purplish blue. The serosal surfaces of both the small and the large intestine were dull, and the loops of intestine were held together by fibrinous adhesions. There were approximately 300 cc. of bloody fibrin-flecked fluid lying free in the abdominal cavity. There were a few fibrous adhesions in the left pleural cavity. The pericardial serosa was smooth and the sac contained 25 cc. of clear amber fluid.

The heart weighed 400 Gm., owing mainly to left ventricular hypertrophy. The endocardium, myocardium and valves appeared normal. The coronary ostia were patent but exhibited a moderate amount of atheromatous thickening. The coronary arteries were widely patent throughout but contained a few yellow atheromatous plaques near the orifices. The abdominal aorta was markedly atheromatous, the condition increasing in severity from above downward. Many large plaques were ulcerated and calcified, and three of these contained tamponade thrombi.

Examination of the orifice of the left renal artery revealed a firm narrow opening, into which a probe could be inserted only with difficulty, the obstruction being due to an atherosclerotic plaque extending about 7 or 8 mm. distally into the vessel (fig. 2). The remaining portion of the artery was not sclerotic. This plaque was firm and completely circumscribed the orifice, so that the lumen could not be distended (fig. 3). The stump of the right renal artery showed no atherosclerosis.

The left kidney weighed 200 Gm. and contained several retention cysts filled with clear amber fluid. The cut surface bulged moderately. The capsule stripped with slight resistance, showing in places a finely granular surface. On the surface were several yellowish white areas, 1 or 2 mm. in diameter, containing purulent material. The cortex averaged from 6 to 7 mm. in thickness. The cortical rays were indistinct. The medulla appeared normal. The entire pelvic mucosa was slightly hyperemic and a few submucosal hemorrhages were present. The prostate gland was not enlarged and the prostatic part of the urethra was not obstructed. The urinary bladder contained a hemorrhagic and purulent exudate.

Fig. 3.—Orifice of renal artery (indicated by arrow).

There was hypostatic congestion in the lungs. The liver weighed 1,350 Gm. and showed only acute congestion. The walls of both the small and the large intestine were thicker than usual because of mucosal and submucosal edema and hemorrhage. This change was more marked in the lower portion of the ileum and in the colon.

No other pertinent pathologic changes were observed. The brain and spinal cord were not examined.

Death resulted from acute focal necrosis of the myocardium. **Microscopic Examination.**—The vascular changes in the kidney were confined to the small and the middle-sized arteries. Moderate thickening of the muscular coats and thickening of

the intima narrowed the lumen in some of the arteries. Reduplication of the elastic lamina, fibrosis and cellular infiltration of the blood vessels were absent. The arteriolar walls showed no changes. Throughout the interstitial tissue were scattered areas of inflammatory cells, both polymorphonuclear and mononuclear in type, with a few small abscesses. Although the great majority of glomeruli appeared normal, several in the inflamed areas were freshly but completely hyalinized. The tubular epithelium was well preserved, although some tubules contained polymorphonuclear leukocytes. Areas of hypertrophied renal elements alternated with occasional scars. No intracapsular crescents were seen. Mild interstitial edema was present throughout (fig. 4).

Arterioles in the perirenal and periprostatic tissues and in the pancreas and spleen were markedly hyalinized. One perirenal vessel exhibited fibrinoid necrosis of its intima. The arteriolar changes elsewhere in the body contrasted distinctly with the lack of change in the kidney.

Microscopic changes of acute passive congestion and heart failure were evident in the lungs and liver. Intestinal edema and hemorrhages were observations compatible with uremia. Areas of early acute myocardial necrosis were present without inflammatory reaction. Except for the hemorrhagic and inflammatory lesions in the bladder and the intra-acinar polymorphonuclear reaction in the prostate, no pertinent changes were observed elsewhere in the body.

COMMENT

It is probable that this patient had a normal blood pressure prior to and for several months after the removal of the ruptured kidney. It was first noted that his blood pressure was elevated eight months before his death. In view of the moderately impaired renal function three months prior to death, it is likely that the renal function was normal before the accident.

The chief point of interest is the relative intactness of the renal parenchyma and the partial occlusion of the renal artery in a person with severe hypertension. From the pathologic description it is plain that the degree of anatomic change in the kidney was not sufficient alone to account for the high blood pressure.

The removal of the ruptured kidney threw the burden of work on the remaining one. Ordinarily one kidney is well able to maintain normal renal function. However, according to Goldblatt interference with the blood supply to a single kidney in dogs and in monkeys produces a permanent rise in the blood pressure. In our case also this occurred. The atheromatous plaque protruding into the lumen of the renal artery near its orifice from the aorta probably played the part of a clamp and cut down the flow of blood to the kidney. In addition, the fact that the kidney hypertrophied very little during the two years after removal of its mate suggests an inadequacy of blood supply. The impaired urea clearance twenty-one months after nephrectomy also points to reduced renal blood flow. However, the ischemia was not severe enough to cause atrophy.

Unfortunately the quality of renal function was not determined prior to the onset of hypertension. However, the urea clearance of the one kidney after the rise in pressure was good enough to suggest strongly that the function would be well within normal limits had the right kidney been present with a normal blood flow. The microscopic structure of the ruptured kidney showed that it was perfectly free from inflammatory, congenital or degenerative changes.

The inflammatory reaction in the remaining kidney consisted of fresh pyelonephritis and appeared to be responsible for the fresh hyaline changes in several glomeruli that were caught in the inflammatory process. The pyelonephritis was terminal, a secondary manifesta-

tion of the cystitis which appeared three weeks before death. Prior to this terminal episode, the urine contained only an occasional leukocyte.

The relatively short duration of the hypertension is borne out clinically by the lack of advanced changes in the retinal blood vessels and pathologically by the relatively small increase in the size of the heart. The coronary arteries were in good condition and probably could not have interfered with hypertrophy of the myocardium.

The unusual degree of arteriolar thickening in the perirenal and periprostatic tissues, pancreas and spleen and the small amount in the kidney are similar to the anatomic changes observed by Goldblatt in his hypertensive dogs. It is thought that in dogs these changes

Fig. 4.—Section of kidney removed at necropsy (hematoxylin and eosin stain).

result from an increase in pressure throughout the arterial system except in the kidney, where the pressure is probably decreased by the narrowed renal artery.

Only information as to the time of the appearance of the atheromatous plaque in the renal artery is missing to make this case completely analogous to experiments in which one kidney is removed before or after the artery to the other kidney is clamped. This case represents the type of hypertension that occurs when ischemia of a kidney is mechanically produced. It does not explain the hypertension that is found in persons with intact renal arteries and kidneys.

This case illustrates another hazard accompanying nephrectomy in aged subjects.

CONCLUSIONS

In a case in which high blood pressure developed after removal of a ruptured but otherwise intact kidney, an atheromatous plaque was observed partially occluding the opposite renal artery.

Except for terminal pyelonephritis, the remaining kidney was relatively free from vascular, degenerative or inflammatory changes.

The situation is analogous to experiments in which hypertension is produced in dogs by partially clamping the artery to one kidney and removing the other kidney.

No analogous case was found in the literature.

THE PELVIC JOINTS DURING PREGNANCY AND LABOR

DONALD J. THORP, M.D.

AND

WILLIAM E. FRAY

Technician

SEATTLE

Since ancient times there has been a sustained interest in the role of the pelvic joints during pregnancy and labor. Hippocrates, Avicenna, Pare, Vesalius, Mauriciau, Smellie and Baudelocque¹ were fascinated by the potential influence of gestation on the pelvic articulations. A review of the modern literature reveals a perennial inquisitiveness equal to that of the

Fig. 1.—Primipara with a 2 to 3 mm. symphyseal span prior to the onset of labor.

ancients. Since 1920 no less than 200 publications have appeared on this subject. X-ray studies have engendered in recent years a renaissance of attention not only to the joints of the pelvis but also to greater precision in pelvimetry, the mechanics of pelvic inclination, cephalometry and the anthropologic significance of pelvic types. For over thirty years the roentgenogram has been used for pelvimetric studies, and such studies have culminated in the masterful work of Thoms,² Jarcho, Caldwell,³ Moley⁴ and others.

From the obstetric and radiology departments of the Swedish Hospital, Read before the Section on Obstetrics and Gynecology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

Interspersed throughout the many splendid contributions to osteology and mensuration of the female pelvis are scores of reports on the spontaneous separation of the symphysis during labor. Frequent reports of sacro-iliac trauma are also available. This report is not concerned with the obviously traumatic separation of the symphysis. We have confined our observations entirely to physiologic diastasis.

Duncan⁵ in 1868 described normal sacro-iliac separation in cows at term and reflected on a potentially similar phenomenon in woman. It is common knowledge that the guinea pig and other lower animals undergo physiologic separation of the symphysis in labor. Baudelocque,¹ examining some twenty women who died in labor, found no pelvic diastasis. Cantin⁶ found increased mobility in the joints of 490 of 500 pelvises during pregnancy. Lynch⁷ observed a constant widening of the sacro-iliac spaces during pregnancy. Roberts⁸ stated that additional separation of the pelvic bones in labor is very slight as observed in a few cases, and he observed that an extreme Walcher position effects no additional widening of the symphysis. De Lee⁹ concluded that "since it requires the enormous force of from 400 to 2,600 pounds to disrupt the pelvic girdle, some inherent weakness of the joints must pre-exist." Thoms² observed no relationship between the amount of symphyseal widening and pelvic type, i. e. gynecoid, android, anthropoid, platypelloid or flat, but he stated that relaxation of the ligaments and joints is greatest in the last half of pregnancy. Bertin¹⁰ inferred from x-ray studies that "contracted pelvises, especially the justominor and funnel varieties, because the expulsive force acts in the narrow transverse diameter, predispose to separation of the pubic bones." Abramson, Roberts and Wilson¹¹ expressed the belief that the symphysis widens an average of 7 or 8 mm. in pregnancy and that the maximum separation is reached between the fifth and the seventh month. In contrast, Reis, Baer, Arens and Stewart¹² were unable to demonstrate any change in the pubic articulations of eighty consecutive women. They concluded that any increase in the span of the pelvis takes place only during labor.

In a previous roentgenographic study¹³ of a small series of pregnant women, it was found that relaxation of the pelvic joints in pregnancy is not sufficient to enlarge the pelvic girdle enough to convert potentially difficult labor into uncomplicated labor. Although a vast amount of investigation has been conducted concerning the influence of pregnancy on the pelvic joints, there has been no inquisition as to the effects of mobility of joints on the course of labor. The literature has not revealed to us studies by roentgenograms contrasting in any given patient the antepartum status of the pelvic joints with their status in labor. Lynch has compared roentgenograms of the symphysis of non-pregnant controls with similar pictures of parturient women.

With this in mind, we studied a series of patients for whom roentgenograms were made near term and

again, in identical views, during the first stage of labor. Our purpose was, first, to determine whether any intrapartum separation of the pelvic joints occurs. Secondly, we sought to determine whether physiologic separation might effect an increase in the area of the superior strait which might expedite the course of labor.

Fig. 2.—The patient shown in figure 1, with a 9 mm. span at the symphysis after five hours of active labor.

Roentgenograms were made of each patient during the last two or three weeks of pregnancy. The patient was frequently placed in the supine position that adequate visibility of the articulations might be secured. For the purpose of studying the influence of mobility of the joints on the area of the superior strait, pelviograms, after the method of Thoms, were made. For

these the lumbar spine was arched in order to bring the plane of the inlet parallel to the plane of the x-ray table. Next, careful measurements were taken from fixed bony landmarks¹⁴ to the plane of the table, in order that the perforated lead grid might be placed exactly at the position of the inlet after the patient left the table. The lead grid is solely to imprint the film with dots at centimeter intervals for convenience of mensuration. A second picture was taken at the height of a uterine contraction after the first stage of labor was well advanced. For this film the position of the patient, exposure time, target distance and voltage were identical with those employed for the initial pelviogram.¹⁵

Seventy-eight cases were analyzed. Those involving complications of pregnancy or labor were discarded and

14. Anterior landmark, central point of upper border of symphysis; posterior landmark, depression below fifth lumbar spinous process.

not included in this total. X-ray pelvimetry revealed no well defined deviations from normal in the series. No inductions of labor were instituted, although sixteen patients were from three to sixteen days postmature, and premature rupture of the membranes occurred in four primiparas. The age range was from 19 to 37 years. All the women were white (table 1).

As attention is directed largely to the first stage of labor, the details of the second and third stages will not be unnecessarily elaborated. An analysis would not be complete, however, without the figures for these stages (table 2). Multiparity seemed not to be of

significance in our eventual conclusions. While the size of the infant might be expected to be an influence and lead to erroneous conclusions regarding the pelvic joints during labor, there was no correlation between supernormal weight and maximum separation of the pelvic articulations. The infants weighed from 5 pounds 1 ounce (2,296 Gm.) to 9 pounds 14 ounces (4,479 Gm.). Some of the maximum symphyseal separations occurred in patients who were delivered of babies of less than 6 pounds (2,850 Gm.).

Of the seventy-eight patients studied, thirty-four were shown to undergo definite diastasis of the symphysis, an incidence of 43.6 per cent (table 3).

Fig. 3.—Primipara with a 2 mm. span at the symphysis before labor.

The average span in the articulations was 5 mm., while one patient had a 12 mm. symphyseal separation. Twenty-one women showed separation in the sacro-iliac joints of 2 or 3 mm. In a few patients we observed this widening in the sacro-iliac joints when no separation of the symphysis occurred. However, separation was usually found in all three articulations. The right sacro-iliac span was commonly wider than the

left. This asymmetry of mobilization is not satisfactorily explained.

Intrapartum changes in the area of the superior strait could not be demonstrated as a result of separation in any of our roentgenograms. This holds even for the woman with a separation of 12 mm.

Fig. 4.—The patient shown in figure 3, with an 8 mm. separation of the symphysis after three and one-half hours of labor.

At the beginning of this work we intended only to determine the incidence of visible physiologic separation of the pelvic joints in labor and its effect on the area of the inlet. After a number of antepartum examinations had been made with the dual x-ray technic described, it was considered of equal interest in subsequent cases to correlate the pelvigraphic observations with a close study of each course of labor. Analysis of seventy-eight cases of the series is shown

TABLE 3.—Analysis of the First and Second Stages of Labor According to Separation or Nonseparation *

	Separation: Average: 5 Mm. 34 Cases (43.6%)		Nonseparation: 44 Cases (56.4%)	
	Primiparas	Multiparas	Primiparas	Multiparas

Average of both.....	9°25'	8°15'	12°12'	6°54'

* A comparison of the two primiparous groups is of special interest.

in table 3, where thirty-four cases of definite separation of the symphysis are contrasted with forty-four in which there was no separation. It will be noted that among primiparas who had definite separation of the symphysis, the average first stage of labor was practically three hours shorter than the average first stage of those without separation. Furthermore, the second stage of labor was definitely longer in all the cases in which there was pubic diastasis. The fourteen multiparas included with the thirty-four women showing separation experienced prolongation of the first stage of labor of one hour and twelve minutes. The ultimate course of labor was consistently more favorable in the primiparas whose pubic joints yielded to the influence pro-

ducing separation, as indicated by the average values for the total of stages 1 and 2.

The twenty primiparas showing separation of the joints were compared with twenty consecutive primiparas from the group of forty-four women who did not show separation (table 4). This demonstrated more directly that those with separation experienced shorter labor than those without separation. Table 4 presents the striking difference in the length of the first stage of five hours and twenty-three minutes. The combined first and second stages demonstrated a difference of four hours and nine minutes in favor of the women with separation.

TABLE 4.—Comparison of Twenty Primiparas from Each Group *

Average.....	9°28'	13°37'	

* Note the difference in the length of the first stage and its influence on the average of stages 1 and 2.

Attention was directed to the apparent influence of symphyseal separation and sacro-iliac mobilization on the course of occiput posterior position. In thirteen of thirty-four cases of separation the infant was in the occiput posterior position in early labor, while this position was revealed in only six of the forty-four cases without separation (table 5).

Spontaneous rotation of the occiput was observed during the first stage of labor in eleven of the nineteen cases of posterior position discovered in the entire series of seventy-eight cases (table 6). Roentgenograms fortunately were secured prior to rotation in nine of the eleven cases. The minimum pubic separation in these nine cases was 7 mm. It is significant

Fig. 5.—A greater separation of the right sacro-iliac articulation than of the left.

that nine of the women experienced spontaneous rotation and at the same time showed a minimum pubic separation of 7 mm. The remaining four patients requiring manual aid showed a separation of only 3 to 5 mm. Only two of the forty-four patients without separation experienced spontaneous rotation. One patient exhibiting a pubic separation of 9 mm., in whom spontaneous rotation took place, was delivered

of an infant weighing only 5 pounds 4 ounces (2,381 Gm.), while another woman experienced spontaneous rotation after we observed an increase of 7 mm. in the symphyseal span and was delivered of a baby weighing 6 pounds 1 ounce (2,750 Gm.). Not one of the babies in the series of thirty-four cases of separation was abnormally large.

COMMENT

The purpose of this study was to determine whether the pelvic joints are mobilized and separated in labor. Separation of the symphysis in labor is frequent enough (an incidence of 43.6 per cent), and wide enough to stimulate speculation as to its cause and its effect. Hisaw¹⁶ expressed the belief that a fraction of the corpus luteum acts on the articular ligaments in lower animals to produce relaxation and marked separation of the pelvic joints in late pregnancy and labor. It is quite possible that a similar hormonal influence is exerted on the human bony structures. Certainly we were dissuaded from concluding from this series that sheer mechanical force, such as might result if the infant was large or if there were tetanic uterine contractions, plays any part. No visible enlargement of the superior strait could be noted in patients with even maximum separation.

It is our belief that in at least nine cases of occiput posterior position there was benefit from physiologic separation of the symphysis pubis in labor. In these nine cases separation was noted preceding spontaneous rotation in labor in all but one, which was roentgenographed after rotation, whereas no pubic separation was noted by roentgenogram from one to three weeks ante partum. Truly this is too small a number from which to draw conclusions governing the multitude, but it does suggest a definite explanation for the frequent autonomous correction of posterior positions.

Finally, there is in our series definite evidence that labor is considerably shortened by the average physiologic separation of the pelvic joints, particularly in the primipara. The multiparas who showed conspicuous separation of the pelvic joints paradoxically had a

TABLE 5.—Presentation and Position
(Early Labor)

longer average labor than those who had no separation. This could be explained by the fact that many of the larger babies were born to these women, and hence retardation of labor resulted from purely mechanical influences.

Concerning the sacro-iliac articulations, it was observed that twenty-one women showed separation of 2 to 3 mm. in one or both joints, the right joint being more commonly involved. As previously stated, however, this asymmetry of mobilization is not satisfactorily explained.

The postpartum effect of joint mobilization was noteworthy only in cases of maximum widening of the sacro-iliac articulations. Three women suffered pain low in the back for several months, requiring the use

of supports. In contrast no woman with even the maximum widening of the symphysis suffered pain or disability in that region after leaving the hospital.

SUMMARY

Physiologic diastasis of the pelvic articulations in lower animals has been demonstrated.

All observations heretofore have been concerned with the influence of pregnancy on the joints. A portion of this report pertains to the influence of separation of the joints on the course of labor.

TABLE 6.—Occiput Posterior Position

	Separation, 34	Nonseparation, 44
Number of patients.....	13 (38.2%)	6 (13.6%)
Spontaneous rotation.....	9* (26.5%)	2 (4.54%)
Roentgenogram previously made.....	8	1
Manual aid required.....	4†	4

* Minimum pubic separation in nine cases, 7 mm.
† Average pubic separation in four cases, 4 mm.

Seventy-eight cases are reported, in thirty-four, or 43.6 per cent, of which there was a definite widening in the symphysis pubis, averaging 5 mm.

No intrapartum increase in the area of the superior strait could be demonstrated.

In thirteen cases of separation of the joints the infant was in the occiput posterior position, and in nine rotation took place spontaneously after a separation of the symphysis of 7 mm. or more.

In four cases of occiput posterior position manual aid (rotation) was required, and x-ray examination previously had revealed an average of only 4 mm. of symphyseal separation.

Six cases of occiput posterior position were observed in the series of forty-four without separation. In only two of these did rotation take place spontaneously, manual aid being required in the remaining four.

In all cases in which there was x-ray evidence of pubic widening greater than 3 mm. the labor was shorter than in the forty-four in which there was no demonstrable widening.

Separation of the sacro-iliac joints was noted in twenty-one women, but no correlation was noted between this condition and the course of labor.

Postpartum sequelae were found in cases of sacro-iliac diastasis, but no subjective or objective symptoms were observed in cases of separation of the symphysis pubis.

Medical and Dental Building.

ABSTRACT OF DISCUSSION

DR. ALICE F. MAXWELL, San Francisco: This report draws attention to the physiologic effects of pregnancy on the pelvic girdle. In recent years, clinical observations and roentgenologic studies have proved that relaxation of the pelvic ligaments and diastasis of the articulations are normal occurrences in pregnancy. Such changes occur so early in pregnancy that mechanical factors as causative agents are eliminated. Research data indicate that articular relaxations in pregnancy are due to hormonal influences. Hisaw in 1929 presented evidence that a secretion of the corpus luteum caused a diastasis of the symphysis in the pregnant guinea pig; he designated this specific secretion "relaxin." Later it was demonstrated that the injection of the serum of pregnant rabbits, dogs, pigs and mares caused a widening of the symphysis in experimental animals in natural or artificial estrus. A similar effect was obtained in castrated male animals subsequent to previous sensitization by estrogen. Recently, identical joint changes have been produced

16. Hisaw, F. L., in Allen, Edgar: Sex and Internal Secretions, Baltimore, Williams & Wilkins Company, 1932, chap. 2.

by injecting pregnant human serum into estrogen-sensitized animals of either sex. This material, as reflected in articular changes, can be demonstrated in the serum of the pregnant woman as early as the eighteenth to the twentieth week; it is invariably present in the middle trimester of pregnancy and is questionably present or absent in the blood in the last trimester. Such evidence connects the hormone with activity of the corpus luteum, yet at present an argument exists as to whether this relaxation is the result of estrogen per se or a synergistic effect of estrogen plus an additional hormonal factor. That estrogen alone can effect pelvic girdle relaxation is shown by x-ray demonstrations of articular diastasis during menstruation and the frequent association of the catamenia with sacral backache. The significance of pelvic girdle relaxation during pregnancy is a matter of interest and speculation to obstetricians. All are familiar with the frequency of symptoms of sacro-iliac strain or slip in pregnancy despite perfect orthopedic balance and abdominal support; occasionally the pregnant woman complains of pain over the symphysis, and in these patients palpation of the articulation during locomotion will reveal a distinct movement of the joint. Diastasis of the pelvic joints inevitably effects an increase of pelvic spacial capacity; and an enlargement of the passages, however minimal, may be a determining factor in the outcome of labor. The advantages of various obstetric postures in labor, often instinctively assumed by the women, are facilitated by ligamentary and articular softenings, for such positions are often unendurable in the nonpregnant female and impossible for the human male. The question of progressive diastasis of the pelvic articulations during labor is problematic. The authors have emphasized that they found no relation between joint separation in labor to the type of pelvis, pelvic diameters or the size of the child. The difficulties of obtaining precise and identical x-ray exposures of the pelvis during the antepartum period and in women during active labor are apparent. Yet such exactness of x-ray studies is essential for comparative pelvic mensuration.

A NEUROLOGIC NOTE ON TRAFFIC LIGHTS

HOWARD D. FABING, M.D.
CINCINNATI

The provocative writings of Lewis Mumford, especially his "Technics and Civilization"¹ and his "The Culture of Cities,"² offer a challenge. In tracing the evolution of the machine, he emphasizes its effect on us as living beings. The machine has grown, he says, independently of biologic considerations; has often made its own rules; has commonly become autonomous—cancerous—to the resultant degradation of man.

Persuasive proofs of this contention are many. The heyday of the rule of the machine over mankind was the period when coal was fuel, steam the prime mover, and iron the essential building material. He calls this, after Patrick Geddes, the paleotechnic period. Dominant roughly between 1850 and 1890, it gave rise to the West's worst cities, Dickens's "Coketowns." They remain as Manchester, Leeds, Birmingham, Merseburg, Essen, Elberfeld, Lille, Newark, Pittsburgh, Youngstown and many more. From gray to black, covered by a dome of smoke which blots out the sun and blackens the lungs of the human beings enclosed by it, these cities remain an architectural proof of the triumph of the machine over the human spirit.

By virtue of technical advance, especially in the development of the water turbine and the widespread use of electrical energy, a new economy, the neotechnic,

began to emerge in the eighties of the last century. The physical characteristics of cities changed with the substitution of water power for coal and electricity for steam, and man profited thereby. But Mumford does not stop at this point. He sees a new relation of man to the machine. This is his biotechnic economy, which he describes as follows:

It refers to an emergent economy, already separating out more clearly from the neotechnic (purely mechanical) complex, and pointing to a civilization in which the biological sciences will be freely applied to technology, and in which technology itself will be oriented toward the culture of life. The key inventions, on the mechanical side, are the airplane, the phonograph, the motion picture, and modern contraceptives, all derived directly, in part, from a study of living organisms. The application of bacteriology to medicine and sanitation, and of physiology to nutrition and daily regimen, are further marks of this order—parallel applications in psychology for the discipline of human behavior in every department are plainly indicated. In the biotechnic order the biological and social arts become dominant: agriculture, medicine, and education take precedence over engineering. Improvements, instead of depending solely upon mechanical manipulations of matter and energy will rest upon a more organic utilization of the entire environment, in response to the needs of organisms and groups considered in their multifold relations: physical, biological, social; economic, esthetic, psychological.

To the skeptical eye this may seem the troubled dream of a utopian and a poet, but in the very poetry of such a vision lies its real worth.

If we look at the machines all about us, and criticize them according to this biotechnic standard, we find that most of them are grossly inefficient, that technically they are not oriented toward the culture of life. The traffic light commonly in use from one end of our civilization to the other is a small case in point. From a purely mechanical point of view it is a most satisfactory device, but from a physiologic standpoint it is utterly bad. Technically there are many better forms of traffic lights already available, but there has been no synthesis of known technical advances in this field with known physiologic data to produce a biologically better traffic light.

The behavior of the motor car driver when he is confronted by a traffic light is the response to a conditioned reflex. Reduced to its simplest terms, the driver is conditioned to step on one pedal with his right foot—the brake—if the light is red, and on another pedal—the accelerator—if it is green. Furthermore, the green light may be classified as an excitatory reflex, prompting forward motion, and the red light may be considered as an inhibitory reflex, calling for a stoppage of forward motion. Therefore, we may call these reflexes those of "excitation" and "inhibition" in the physiologic sense. When regarded singly, each is simple and effective.

However, they cannot be regarded singly because they follow in quick succession and because they are mutually antagonistic. The driver often comes upon a traffic light quickly, and he does not know how soon it will change. Although it may be green at a given second, and thereby prompt him to press down the accelerator pedal (excitatory reflex), he knows experientially that, before he reaches the intersection, the antagonistic conditioning stimulus—the red (inhibitory) light—may have supervened, calling for a different response in the right leg.

2. Mumford, Lewis: *The Culture of Cities*, New York, Harcourt, Brace & Co., 1938.

This quick succession of antagonistic conditioned reflexes and this confusion in visual conditioning stimuli have been studied carefully by Pavlov³ in the dog. He gives the term "collision" to the phenomenon, and he finds that such juxtaposition of excitatory and inhibitory reflexes leads to a pathologic nervous state. In the experimental dog he has shown that "collision" occurs in two situations entirely parallel with those commonly confronted by the motor car driver when he is faced by a traffic signal; first the collision occasioned by the rapid succession of reflexes of excitation and inhibition heaped closely on one another in time; and second the collision occasioned by a confusion of visually similar stimuli. It is well to review his experiments and to compare his results with the human being in like circumstances.

EXPERIMENT 1.—"Collision" resulting from a quick succession of excitatory and inhibitory conditioned reflexes.

A dog was conditioned to respond to a rhythmic mechanical irritation of the skin with the "food reflex." A regular tapping of an area of the dog's skin was repeatedly followed by feeding. Soon the tapping of the skin alone provoked the expectation of food in the dog, as evidenced by a copious flow of saliva, measured quantitatively, and by a turning of the dog's head toward the foodbox. When this reflex became stable, i. e. when rhythmic tapping of a given area of skin invariably provoked the same salivary and motor response, a second conditioned reflex was elaborated in the dog. The same area of skin was used, the same tapping stimulus was used, but the rhythm or rate of tapping was altered. This second stimulus was never followed by the giving of food. Soon the second response became established. It was inhibitory in type, characterized by a cessation of normal salivary flow and a failure to turn the head toward the foodbox. When both reflexes were thus established and defined quantitatively, Pavlov began to apply one stimulus immediately after the other, without any interval; i. e., he began to apply the inhibitory stimulus immediately after producing the excitatory reflex. This led to a striking pathologic state in the dog. The animal, following this "collision" occasioned by rapid succession of antagonistic reflexes, no longer was docile and gentle but became very excited and irritable (nervous). There followed a complete loss of all conditioned reflexes in the animal, and they returned only after many weeks in a paradoxical fashion. The slow return to normal was effected by an actual "treatment" of the dog, which included rest and daily rectal instillations of bromides.

EXPERIMENT 2.—"Collision" resulting from confusion of visually similar stimuli.

A dog was conditioned to respond to food positively by a circle of light flashed on a screen. When the reflex became stable, the stimulus invariably evoked a generous flow of saliva and a turning of the dog's head toward the foodbox: the typical conditioned response, the "food reflex," which Pavlov analyzed so carefully for many years. The dog was then conditioned negatively to a light stimulus of equal intensity but of different shape. The stimulus in this case was an ellipse, of the same intensity and general size as the circle, but in which the diameters were as 2:1. This second reflex, a differentiation of the first, was made stable by repeated trials and came to provoke the typical inhibitory response, a drying up of the normal salivary flow and a failure to turn toward the food source. The negative stimulus was then altered by making the ellipse progressively more circular on repeated trials. The differentiation persisted and functioned properly until the ellipse became almost circular—until its diameters came to be as 9:8. The ellipse then lost its inhibitory character, as did all the other more elongated ellipses. All shapes of ellipses now became excitatory even though no food was offered. The dog, which formerly stood quietly on his bench,

now was constantly struggling and howling. After rest and treatment with bromides, the conditioned reflexes and their differentiation were again elaborated, more slowly and more carefully. However, when the ellipse was contracted again to the place where its diameters were as 9:8, i. e. when it became almost circular, the dog again lost his differentiated response and fell once more into his former pathologic state. The experiment could not be continued; the dog was too upset. He had acquired a condition which Pavlov called a traumatic neurosis.

In the present day traffic light we have a situation that parallels both these experimental instances. The quick succession of stimuli of excitation and inhibition occur in the traffic light changes just as they occurred in experiment 1. The potentially changing color of the light, from red to green or vice versa, leads to a confusion in stimulus similar to the confusion of the stimulus of the circle and the almost circular ellipse in the second experiment. Careful appraisal, furthermore, of one's own bodily reactions, or careful observation

Traffic light consisting of a circular glass panel, illuminated from the rear, divided into colored sectors. The hand, revolving clockwise, shows how much green or red remains.

of the driver of a car in which one is a passenger, leads to the realization that the human being, as well as the dog, "falls into a state of excitation," to use Pavlov's words, following a situation in which a "collision" of traffic light stimuli has occurred. I have noted a quickening of my pulse by twenty-five beats above the normal, a pilomotor response on my forearms, a dryness of the mouth, a sudden excessive sweating of the palms, a feeling of epigastric distress, a sensation of inward tremulousness, and even observable tremor of the extended hands, immediately following such a "collision" on repeated occasions while driving. Occasional quick glances into the rear vision mirror have shown an unusual pupillary dilatation as well.

These observations point to the fact that the human bodily reactions to such a situation represent an autonomic discharge commonly associated with states of excitation and anxiety—that the confusion of traffic light conditioned reflexes leads to what may be called an "anxiety neurosis in miniature." When a whole series of these experiences follow closely on one another after long hours of driving in metropolitan

3. Pavlov, I. P.: *Lectures on Conditioned Reflexes*, translated by W. H. Gantt, New York, Liveright Publishing Corporation, 1928, p. 339 et seq.

areas, there is commonly a prolonged bodily reaction of this kind which produces a conscious restless anxious exhaustion.

What, then, can be done to eliminate this collision of exciting and inhibiting reflexes and the resultant pathologic nervous state? What technical advances are at hand to apply to these physiologic data to make of the traffic light a more efficient biotechnical device?

Inventors have sensed this problem, and there are now in the United States Patent Office patented devices by Altman,⁴ Degner,⁵ Olafson⁶ and Schubert⁷ to improve the traffic light. From a physiologic point of view, the last is probably the best. It is constructed as follows: A circular glass panel, illuminated from the rear, is divided into sectors, the upper green, the lower red, and two small intermediate sectors at each side yellow. A hand, similar to a clock's hand, revolves slowly around the circular panel in a clockwise direction, as shown in the accompanying illustration. The driver may see at a glance how much green or red remains on the panel and by noting the speed of the revolving hand he may respond to the stimulus more rationally. Two stimuli now evolve into a flowing continuum of stimulation rather than a rapid succession of colliding antagonistic patterns. The signal itself, being more graphic, is more easily defined consciously and therefore becomes a more efficient physiologic stimulus.

Traffic lights of this kind are to be seen in operation, though far too rarely. It is altogether fitting that the land of Pavlov's birth should be an early employer of such a device. In the summer of 1934 I saw such a signal in operation at the southern end of the Red Square in Moscow. Another was to be seen in the Bahnhofstrasse in Zurich, Switzerland, in 1937. Perhaps there are many others, but at best there are far too few. The universal adoption of a traffic signal of this or similar type would undoubtedly bring a real measure of relief to the motoring public, for, as Pavlov states, "this conflict and this balancing are not too easy for the nervous system."

SUMMARY

Lewis Mumford has pointed out that in the employing of machines we have too often forgotten their biologic effects in our constant search for mechanical perfection. He envisions a new period in technical history, the biotechnic era, when the machine will be restudied and redesigned on a physiologic basis—oriented toward the culture of life. The ubiquitous traffic light is examined in the light of this criticism and, although its mechanical efficiency is unquestioned, it is found to be bad physiologically—bad for us who have to live with it. The adoption of another form of traffic signal, less exhausting to the nervous system, is desirable.

The Incubus of Galen.—It was in this century that such scientists as Copernicus, Vesalius (1514-1564) and Paracelsus (1493-1541) lived and worked. There was still much medievalism in the beliefs of these men; but they were endeavoring to do, and did, considerable independent thinking. In the domain of medicine all thinkers were struggling to get rid of the incubus of Galen.—Hurd-Mead, Kate Campbell: *A History of Women in Medicine*, Haddam, Conn., the Haddam Press, 1938.

COLD VACCINES

AN EVALUATION BASED ON A CONTROLLED STUDY

H. S. DIEHL, M.D.; A. B. BAKER, M.D.

AND

D. W. COWAN, M.D.

MINNEAPOLIS

Our reasons for adding to the already voluminous literature on the use of vaccines for the prevention of colds are, first, that few studies of these vaccines have been adequately controlled and, second, that in spite of their questionable value cold vaccines are administered to hundreds of thousands of persons throughout the country each year. Physicians in private practice have little or no opportunity to evaluate such preparations and so are apt to base their opinions as to value on the reports of individual patients. On the other hand, organizations such as college and industrial health services, which are charged with the prevention of illness among large groups of persons, have a special interest in colds and have made various attempts to evaluate vaccines and other preventive measures. If vaccines are effective in a considerable proportion of cases and are harmless, they should be used extensively; if not, doctors and patients should cease wasting their time and money on them.

The study here reported extended over a period of three years and included work with one vaccine administered subcutaneously and two administered orally. Until recently all cold vaccines were injected either subcutaneously or intramuscularly, but during the past few years several vaccines for oral use have been developed and are already being widely utilized.

TECHNIC OF STUDY

The subjects were all students of the University of Minnesota who volunteered to participate in the study because they were particularly susceptible to colds. When they reported for their first vaccine treatment, the records of their physical examination were inspected and they were questioned concerning the symptoms which usually accompanied their colds. This procedure was followed in order to exclude from the study persons whose difficulties seemed to be due primarily to chronic sinusitis or allergic rhinitis. At the same time a record was made of each student's recent history of acute infections of the upper part of the respiratory tract, with particular attention to the number and the severity of colds experienced during the previous year and the amount of time lost from school on account of them.

Experimental and Control Groups.—At the beginning of each year of the study students were assigned at random and without selection to a control or to an experimental group. The students in the control groups were treated in exactly the same manner as those in the experimental groups but received placebos instead of vaccine. All students thought that they were receiving vaccine and so had an unprejudiced attitude toward the study. Even the physicians who saw the students at the health service when they contracted colds during the period of the study had no information as to which group they represented.

From the Students' Health Service and the Department of Preventive Medicine and Public Health of the University of Minnesota.
Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

Reporting of Colds.—The students in all groups were instructed to report to the health service whenever a cold developed and to keep a record of each cold of more than twenty-four hours' duration. A report was obtained from each student monthly during the first year of the study and quarterly during the second and third years. The physicians who cared for the students who reported to the health service with colds made notations on their records concerning the severity and the type of the cold in each case. These records were checked later against the reports which were made by the students.

There might be some objection to the use of subjective as well as objective criteria as a basis for the determination of results, but our experience in the study of colds over a number of years indicates that the appearance of the nasal and nasopharyngeal mucous membranes is not so dependable a criterion on which to base the diagnosis of a cold as is the patient's report of his symptoms.

Loss of Time.—At the beginning of the study each student was instructed to keep a record of the number of days which he lost from school because of colds. These reports were collected quarterly and were checked by the conferences which the doctors in charge of the study had with the students.

At the end of each year reports as to the incidence of colds and the time lost from school were summarized according to experimental and control groups.

SUBCUTANEOUS ADMINISTRATION OF VACCINE

No attempt will be made to review the many reports¹ on subcutaneous vaccination against colds. Some of the more uncritical workers have been enthusiastic about the value of these vaccines, but the better controlled studies indicate that little of value can be expected from their use.

Vaccine Utilized.—The vaccine selected for this study was standardized according to the milligrams of nitrogen per cubic centimeter, as follows: pneumococci 0.015 mg., streptococci 0.015 mg., *Bacillus influenzae* 0.01 mg., *Micrococcus catarrhalis* 0.0025 mg. and staphylococci 0.0075 mg. It was prepared by the so-called Kreuger method; that is, the organisms were destroyed mechanically instead of by heat. This method of preparation is supposed to provide a vaccine which is a superior antigen because the bacterial proteins have not been changed by heat. The evidence that the method is of practical value is not conclusive, but this vaccine was chosen for study because it has all the merits of heat-killed vaccines and possibly more.

Gillensward, Curt: Anticatarrhal Vaccination in Homes for Children Under School Age, *Acta paediat.* (supp. 1) 17: 78-90, 1935.

Dosage of Vaccine.—The vaccine was administered hypodermically to the experimental group as follows: 0.5 cc. twice a week for three weeks and then 0.5 cc. every two weeks throughout the fall, winter and spring. The control group received injections of physiologic solution of sodium chloride administered in the same way, at the same intervals and throughout the same period. Our experience indicates that it is extremely important in such a study to treat the control group and the experimental group in exactly the same manner and not to use for control a group of persons who receive no treatment whatever.

Results.—Table 1 presents a summary of the results reported by the students who received the bacterial vaccine subcutaneously and by the corresponding control group during the years 1935-1936 and 1936-1937.

* Reported from memory.

The results have been tabulated so that comparisons can be made for each year separately as well as for the total experimental period.

Two hundred and seventy-two students in the vaccinated group and 226 in the control group completed the study, representing 92 per cent and 87 per cent, respectively, of the number who began it. These are high percentages in view of the fact that a considerable number of university students drop out of school during the course of the year for scholastic or other reasons.

The uniformity of the average number of colds which the students in the several groups reported that they had during the year prior to the study indicates that the groups were well equated so far as susceptibility to colds is concerned.

During the two years of the study the experimental group reported an average of 1.6 colds a person yearly. This represents a reduction of 73 per cent from the average of 5.9 colds per person which the same students reported for the year prior to the study. Such a reduction would seem to be definite evidence of the value

of the vaccine. However, when we turn to the summary of the reports from the control group we find almost as great a reduction; namely, from an average of 5.6 colds per person for the year prior to the study to 2.1 colds per person yearly during the period of the study. This is a reduction of 63 per cent and is as much as has been reported by most writers who recommend the vaccine.

TABLE 2.—*Subcutaneous Vaccination in Relation to Frequency of Colds*

	Less Than Six Colds in Previous Year*		Six or More Colds Previous Year*	
	Vaccinated Group	Control Group	Vaccinated Group	Control Group

Average number of colds during year of study	1.6 \pm 0.06	2.0 \pm 0.07	1.6 \pm 0.08	2.2 \pm 0.11
Difference between experimental and control groups.....	0.4 \pm 0.09	0.6 \pm 0.14
Percentage.....	-20.0	-27.0

* Reported from memory.

The difference between the average number of colds per student in the experimental and in the control groups during the two years of the study is 0.5 ± 0.08 colds per person yearly. This difference in favor of the vaccinated group, although statistically significant, is too small to be of practical importance. A similar comparison of the median number of colds reported by the experimental and by the control groups gives even less evidence of value of the vaccine.

The average and the median number of days lost per person from colds is essentially the same for the vaccinated and the control groups. The proportion of subjects who reported no colds whatever during the

period of study was 11 per cent for the control group and 20 per cent for the vaccinated group. If this group is excluded from our computations, we find that the average number of colds per person among those who had any colds was 2.5 for the vaccinated group and 2.7 for the control group. In other words, the margin of benefit in the vaccinated group is represented entirely by the difference of 9 per cent in the number who had no colds whatever.

In an effort to determine whether the reduction in colds was occurring in any particular group an analysis was made of the results among students who reported six or more colds as compared to those among students who reported less than six colds during the previous year. Table 2, which presents this analysis, shows no significant differences between the groups.

A few students participated in this study during both the years in which it was conducted. Twenty-five of these were in the control group the first year and in the vaccinated group the second year, thinking, of course, that they were receiving the same vaccine the two years. Table 3 shows that this group reported an average of 2.6 colds during the year in which they were in the control group and 1.9 colds during the year in which they were in the vaccinated group. On the other hand, thirty students who were in the vaccinated group the

first year and in the control group the second year also reported somewhat fewer colds during the second than during the first year (table 3).

Thinking that the students benefited might be those who were sensitive to some of the organisms in the vaccine, we made an intracutaneous test with the vaccine on all subjects at the beginning of the study. The results, as shown in table 4, do not indicate that this procedure is useful in identifying the persons who may expect benefit from the vaccine.

ORALLY ADMINISTERED VACCINE

Rockwell, Van Kirk and Powell² have reported several studies which suggest that vaccines containing organisms of the respiratory group administered by mouth may be useful for the prevention of colds. Their studies contain control groups, but the subjects in these groups apparently received no treatment whatever. If this inference is correct, the results which this group reports cannot be accepted as comparable to the results reported by the experimental groups.

2. Rockwell, G. E.; Van Kirk, H. C., and Powell, H. M.: Oral Immunization to Colds, *J. Immunol.* **28**: 475-483 (June) 1935; Further Studies on Oral Immunization to Colds, *J. Lab. & Clin. Med.* **22**: 912-917 (June) 1937.

Through the courtesy of the producers, two types of cold vaccines for oral administration were studied. One of these is available commercially and widely used throughout the country; the other has been prepared and used more or less experimentally by Dr. E. C. Rosenow of the Mayo Clinic.

Polyvalent Vaccine for Oral Administration.³—This vaccine, containing 25 billion pneumococci, 5 billion *Haemophilus influenzae*, 15 billion streptococci and 5 billion *M. catarrhalis*, was used during the winters of 1936-1937 and 1937-1938. During the first year in which the orally administered vaccine was used a control group was receiving sterile saline solution hypodermically. This group, it was decided, could justifiably serve as a control for the orally administered vaccine. During the second year of the use of this vaccine a special group to serve as a control was set up. The subjects in this group were given lactose-filled capsules which were indistinguishable from the capsules containing the vaccine. They were prescribed with exactly the same instructions as the capsules containing the vaccine.

* Reported from memory.

The directions for taking this vaccine were as follows: "The capsules must be taken on a resting and empty stomach. Take one capsule with a drink of cold water one hour before breakfast. One capsule must be taken each morning for seven consecutive mornings and then two capsules weekly throughout the season."

Each student was given a supply of capsules sufficient to last eight weeks, at the end of which time he returned to the health service for a new supply. This enabled the physicians in charge of the study to check on the actual use of the capsules by the students.

Results.—The method of reporting results was the same as that which has been described for the vaccine given subcutaneously. The tabulation of the reports (table 5) shows a reduction for the vaccinated group of approximately 70 per cent in the average number of colds per person for the year of the study as compared to the previous year. This is approximately the same reduction that was reported by Rockwell and

his associates. However, when we turn to our control group we find just as much reduction as was reported by the vaccinated group. In other words, this study shows that in the average or the median number of colds per person yearly, in the number of days lost from school and in the proportion of students who had no colds during the period of the study, there is no evidence of any benefit whatever from the vaccine.

Streptococcus Vaccine.—Dr. E. C. Rosenow,⁴ who has been experimenting with several types of vaccines, supplied us with a streptococcus cold vaccine which he had prepared for use by mouth. The streptococci in this vaccine were isolated from the nasopharynx or sputum of patients with common colds. The final concentration of the vaccine contained 20 billion organisms per cubic centimeter. It is put up in a corn syrup vehicle. The first dose was 5 drops daily, taken preferably from a half to one hour before breakfast. This dose was increased by 5 drops daily up to 20 drops; then 20 drops was taken once or twice weekly throughout the winter.

During the year in which this vaccine was studied a control group was taking lactose-filled capsules. This group, it seemed, could serve satisfactorily as a control for both orally administered vaccines and was so used.

* Approximately half as many subjects as in the other groups.

The results reported with this streptococcus vaccine (table 6) parallel exactly the results reported by the control group.

Untoward Symptoms.—Table 7 shows a summary of the symptoms which the students attributed to the orally administered vaccines during 1937-1938. It will be noted that although relatively few students reported any such symptoms there is a distinct differentiation between the groups in this regard.

3. The firm which developed this vaccine was interested in its further evaluation and supplied us with the vaccine used in this study.

4. Rosenow, E. C., and Heilman, F. R.: Streptococcal Vaccines in the Prevention and Treatment of Respiratory Infections, *Am. J. Clin. Path.* 8: 17 (Jan.) 1938.

COMPLICATIONS

It has been stated frequently that, even though bacterial vaccines may have little or no value for the prevention of colds, they probably reduce the frequency and the seriousness of complications. Table 8 presents a summary of what might be considered complications from acute colds as these were recorded on the health service records of the several groups of students. Since some of the subjects lived at home, this report is not complete. On the other hand, it would seem that by groups the data should be relatively comparable. The larger number of complications reported by both groups which received "oral vaccine" and by the control groups during the last year of the study indicates that the acute infections of the upper part of the respiratory tract were more severe and of a different type during the last year than during the earlier years of the study. The number of cases involved in the several groups is too small to justify the drawing of conclusions, but certainly this table presents no evidence that the vaccines reduced the complications among these particular students.

CONDITION OF NOSE AND THROAT AND
FREQUENCY OF COLDS

Every student included in this study had had a nose and throat examination by an otolaryngologist of the

health service staff, in most instances within two months of the beginning of the study. Table 9, which presents a summary of the reports in accordance with the recorded condition of the nose and throat, gives no support to the impression that students with nasal obstruction or infected tonsils are unusually susceptible to colds.

COMMENT

These studies were so planned that the reports of results would be made without prejudice on the part of either the patient or the physician. Tabulations were made for each year separately without the persons who made the tabulations having the summaries of the previous years at hand. The students were not under such constant supervision or subject to such accurate checks of absences due to illness as are certain groups of industrial employees. On the other hand, these students made intelligent, cooperative and conscientious subjects. Hence it would seem that the results here presented are sufficiently dependable and sufficiently well controlled to serve as a basis for conclusions.

Statistical analysis of the results reported for the subcutaneously administered vaccine shows that the differences reported are statistically significant and indicates that this vaccine has a definite biologic effect. However, in a group such as this, selected on the basis only of susceptibility to colds, the beneficial effect is too small to be of practical value. On the other hand,

further studies to determine how, why and for what persons the vaccine is of value are clearly indicated. If such studies should make it possible to select for vaccination the persons most likely to be benefited, it is possible that the average effectiveness of the vaccine could be greatly improved.

During the winter of 1936-1937 Drs. T. B. Magath and Joseph Berkson⁵ of the Mayo Clinic conducted a study of oral vaccination⁶ very similar to the one here reported. The subjects of their study consisted of doctors, nurses, stenographers, clerks, technicians and other employees of the Mayo Clinic. The experimental and the control groups were carefully equated and treated in a like manner. As in our study, the control group received lactose-filled capsules which they thought contained vaccine. All subjects kept accurate records of their colds, on which they reported each month.

A tabulation of these results shows an average of approximately 18 per cent less colds per person in the vaccinated group than in the control group. Just why Magath and Berkson obtained this evidence of slight benefit from the orally administered vaccine when our study shows none, it is difficult to say. The benefit may have been due, at least in part, to the differences in the ages and in the average susceptibility to colds of the subjects or to differences in the methods of collecting reports. For practical purposes, however, the results which they obtained and those which we are reporting are not at variance. In fact, the results with the orally administered vaccine are almost identical with those which we obtained with the subcutaneously administered vaccine. With this the average number of colds per person was 25 per cent less for the vaccinated group than for the control group, but who would advocate either the expense or the inconvenience of taking cold vaccines throughout the fall, winter and spring in order to reduce by 25 per cent the probable number of colds that one might have during the year?

SUMMARY AND CONCLUSIONS

In a carefully controlled study of the value of three different vaccines which are recommended for the prevention of colds the subjects were cold-susceptible students of the University of Minnesota.

A "control group" was observed during each year of the study. Such groups were chosen at random from the students who applied for cold prevention treatment; the members were treated in exactly the same manner as those of the vaccinated group, and they believed throughout the period of the experiment that they were receiving vaccine. Sterile physiologic solution of sodium chloride was administered hypodermically as a control for the subcutaneously administered vaccine and lactose filled capsules as a control for the vaccines administered orally.

One of the most significant aspects of this study is the great reduction in the number of colds which the members of the control groups reported during the experimental period as compared to the number that the same students reported for the previous year. In fact, these results were as good as many of those reported in uncontrolled studies which recommend the use of cold vaccines.

The group which received vaccine subcutaneously experienced an average of 25 per cent less colds per

5. Personal communication to the authors.

6. The vaccine which they studied was the same polyvalent oral vaccine that was used in this study.

person than did the control group. This difference occurred during both years of the study and is statistically significant. Practically, however, it is of little or no importance, because a reduction of 25 per cent in the average number of colds in a group of individuals is not sufficiently great to justify the time and expense involved in carrying out the intensive vaccination procedure which was utilized.

The group which received the polyvalent vaccine administered orally experienced just as many colds as the control group during both years of the study.

The results reported by the students who took Rosenow's streptococcus vaccine parallel exactly those reported for the control group.

Although the data are not entirely conclusive, there is no evidence in this study either that vaccines reduce the complications of colds or that the condition of the nose and throat is related to the frequency of colds in a cold-susceptible group.

ABSTRACT OF DISCUSSION

DR. W. A. SAWYER, Rochester, N. Y.: The investigation of the authors is proof of how easy it is to jump to conclusions and make deductions on too little evidence. I have been guilty of concluding that because a patient reported no colds after taking a vaccine it was probably the result of the vaccine. Again and again one hears doctors say that they believe vaccines against colds are about 50 to 70 per cent effective. Such statements are based on evidence of very few cases, and almost always without a control study. Dr. Diehl and his co-workers have exercised much care in eliminating any personal psychology. What the individual feels or imagines has had too great an influence. In 1930-1931 in Rochester subcutaneous cold vaccines were given to a small group, with the result that 42 per cent reported no colds or mild colds. In all the work I have advised vaccines only to those who are highly susceptible. This 42 per cent looked encouraging. In 1931-1932, 45 per cent reported no colds or mild colds, again a figure giving some hope. In 1932-1933 the same percentage was obtained, 45. In 1933-1934 it was only 40 per cent. From such figures I think any one might assume that vaccines have been of some real value, particularly when given to persons who have previously had numerous colds. At least the percentages are rather consistent in these four different groups. Likewise, the percentages of those not helped were consistent, being 13, 15, 18 and 16. In 1934-1935 vaccines were given to 115 cold-susceptible employees, with the result that 57.4 per cent reported no colds or mild colds. This looked even more encouraging; however, this time there was a control group, but not to the extent that Dr. Diehl and his co-workers had. This control group did not receive anything to prevent colds, not even a placebo. Records were carefully kept of their colds and 46.8 per cent of them reported no colds or mild colds. This gives a slight margin of value to the vaccine, but not sufficient to warrant its general use. You see how different the picture looks with a control. This control group rated higher than any of the groups in any of the previous years. All of this looks rather encouraging, if one does not question what might have happened if they had not taken anything. We owe a debt of gratitude to Dr. Diehl and his co-workers for their valuable investigation.

DR. L. D. BRISTOL, New York: Throughout industry we have been attempting to appraise the value of these cold vaccines for some time, but, as Dr. Sawyer has indicated, it is often difficult to set up a controlled experiment of this sort in industry. Last fall I reported 20,000 instances of vaccinations against the common cold among six of our operating companies in the Bell system, covering an experience of from five to seventeen years. This was not a controlled experiment in any sense of the word but simply a study of what appeared to be the results; from that study we arrived at practically the same conclusions as Dr. Diehl and his co-authors have presented here; in other words, no apparent reduction in the

incidence of colds. The only way in which my study differed, slightly, from the authors' results was in finding some evidence of a reduced length of disability from work and some less severity and complications of colds among those who had received these vaccines. Such groups as the authors' in our universities are the ones to give the results of such scientifically controlled experiments. Their study goes a long way toward determining the real value of these cold vaccines.

DR. J. E. NELSON, Seattle: How do you account for the lower number of colds in the vaccinated and the controlled groups during the study than what they reported in the previous years?

DR. ROBERT K. CUTTER, Berkeley, Calif.: All reputable biologic laboratories welcome controlled studies of their products. Clinicians are often optimists and to control their overenthusiasm we urge the use of a placebo and the product to be tested, labeled only by numbers, the "key" held by a notary until the study is complete. It is unfortunate that Dr. Diehl and his co-workers used the Krueger antigen rather than the standard bacterial vaccines used in most other studies of cold vaccines, particularly as Dr. Singer-Brook reported at the American Academy of Pediatrics last week that in a study of whooping cough immunizing products the Krueger antigen group showed no greater immunity than the control group, while the group immunized with phase one vaccine, which is a true bacterial vaccine, showed definite immunity. This certainly does not prove that bacterial vaccine injections would prevent colds but it does indicate that a study involving Krueger's antigen does not evaluate the usual bacterial vaccines. I hope that Dr. Diehl and his co-workers will have an opportunity to study the worth of unmodified bacterial vaccines by injection in the future.

DR. H. S. DIEHL, Minneapolis: The results, I admit, were distinctly disappointing. We had hoped to find among these vaccines a specific preventive measure to reduce the incidence of colds. Dr. Sawyer's experience in connection with employees of the Eastman Kodak Company is enlightening and critical and, as he points out, shows again the necessity of having a control group before one is justified in drawing conclusions in a study of this sort. Individual opinions, as these studies show, mean nothing. During the course of this study several physicians have written or called us to say "I have a patient who was a student at the university last year and took your cold vaccine and got such splendid results that he wants to continue it. Will you be good enough to tell me what vaccine you are using?" And we would look it up and find in many instances that the person in question got the sterile saline solution or the lactose capsules. In answer to the question as to how we explain the smaller number of colds during the year of the study than during the previous year, this, I think, is merely evidence that none of our memories are accurate as to the number of colds we had a year ago. Furthermore, during the year of the study we gave each student a definition as to what to consider a cold. These were that "You are to record the condition as a cold only if the symptoms last twenty-four hours or longer. If you have a little coryza for half a day and it is gone, do not consider that a cold. These probably are the reasons for the fewer colds during each experimental period than during that previous year. These differences appear for the control groups as well as for the vaccinated groups. As to the use of heat-killed vaccine, we have no evidence that the heat-killed vaccine might not be better than the Krueger type vaccine, prepared without the use of heat. On the other hand, we assumed that if we were to use the heat-killed vaccine there might be some suggestion that the so-called undenatured antigen would be better, while if we used this mechanically killed and undenatured antigen the results would be applicable to the heat-killed vaccine as well. If this study did not accomplish anything else, it demonstrated the importance of treating "control" groups in exactly the same manner as experimental groups. In such preventive or therapeutic studies it is not sufficient to use for control purposes groups which are merely observed. They must be treated in exactly the same manner as the experimental group if the results are to have significance.

HYPERTENSION AND HEALTH
DIAGNOSIS

A STUDY OF ONE HUNDRED CASES

WILLIAM R. P. EMERSON, M.D.

BOSTON
AND

J. GRANT IRVING, M.D.

Consultant in Physical Fitness and Assistant Medical Director,
Respectively, Aetna Life Insurance Company
HARTFORD, CONN.

The following study of hypertension was made from the point of view of health diagnosis, namely, determination of the causes of impaired health that may or may not be the causes of disease.

The data for individual health diagnosis were obtained from five sources, as follows:

(a) A health history, to ascertain causes of impaired growth and development and of nervous instability.

(b) A physical fitness examination, to determine the present state of health and the physical defects.

(c) A check-up of the twenty faulty health habits which were found by clinical work with so-called healthy adults to be the most serious causes of impaired health.

(d) A check-up of daily programs of living from the time of rising until bedtime at night.

(e) A check-up of food habits, including the total daily intake of calories, the amount taken at each meal, the balance and the vitamin content.

The physical fitness examination includes the usual medical examination to exclude disease in order to evaluate the effects of faulty health habits. The physical check-up was uniform for every man examined and covered approximately 100 points of significance in determining causes of impaired health. Forty of these points were checked in the health history and thirty in the physical examination, and thirty were concerned with faulty health habits.

In judging physical fitness we have found weight for height¹ a valuable measure of optimum health, as is shown by chart 1. It will be seen that for the earlier ages mortality increases for persons below optimum weight, while for the later periods of life it increases for those above optimum weight. That range of weight is considered optimum for which there is the lowest mortality, from 5 to 15 per cent above the average weight for height.

Chart 1 shows the danger of overweight at the older ages, mortality increasing approximately 1 per cent for each pound above optimum weight. It is important to remember that the average weight of the actuarial table is not normal weight. At our first physical examination we explained the relation of weight to height and the desirability that persons in the danger zones of overweight and underweight obtain optimum weight as a standard of physical fitness.

Our physical fitness service was offered to the executives and employees of the Aetna Life Insurance Company at their home office. The definite results obtained by the correction of both the physical defects and the faulty health habits of the first 642 men taking the service were evidenced by a prompt improvement in their general condition: 199 overweight men reduced their weight 1,079 pounds (488 Kg.), and 259 underweight men gained 802 pounds (364 Kg.). Also there

was a reduction of 51 per cent in days off from sickness. Because of these results the service was later offered the larger policyholders of the company.

In the course of this work 120 men were found to have a systolic blood pressure of 143 mm. or over. Twenty did not return for a second reading.

This study has to do with 100 men with hypertension who followed our program: seventy-seven of the first 815 executives and employees examined and twenty-three of the first 205 policyholders examined. The men in the first group made an average of twenty visits to the department during a period of from one month to five years, and those in the second group made an average of ten visits in a period of from two months to two years. The first readings were taken at the first examination and the last readings at the latest visit.

Because of the relation of weight to mortality, which is recognized in insurance work by rejection or sub-

Chart 1.—Influence of weight on mortality. The figures on the curves represent the percentage of mortality for the respective ages and weights. In the early twenties mortality increases about 1 per cent for each pound below average weight for height. Above the age of 35 mortality increases about 1 per cent for each pound above optimum weight.

standard ratings on this factor alone, we have separated these groups into three divisions: overweight, optimum weight and underweight, as shown in table 1.

The health of these groups, according to their own ratings, is shown in table 2. Apparently 90 per cent of the men with hypertension considered their health above the average and 58 per cent considered their health optimum. Only 3 per cent considered their health below average, and none considered it poor.

Table 3 shows an average of less than one physical defect per subject. Excluding cerumen, carious teeth, hernia, flatfoot, varicocele, varicose veins, and cyst, which evidently are not factors in causing high blood pressure, we have a total of forty-seven defects which may be contributory causes, an average of 0.5 defect per subject. Thirty-four of the men were referred to their own physician and fifty-seven to their own dentist.

1. Emerson, W. R. P.: *The Diagnosis of Health*, New York, D. Appleton & Co., 1929.

The number of faulty health habits according to weight groups is shown in table 5. The optimum weight group had the fewest and the overweight group the greatest number of faulty health habits. The most common faulty health habits in the overweight group included overeating, fast eating and the taking of insufficient exercise, while the underweight group exceeded in habits of overactivity and fatigue. Overeating was common, as indicated by the large proportion of overweight men.

The ratio of physical defects to the number of faulty health habits was 1 to 4. Exclusive of physical defects not factors in hypertension, the ratio was 1 to 6. Since a faulty health habit may be as serious in causing impaired health as a physical defect, this ratio is significant.

Data additional to those obtained by checking the physical defects and faulty health habits were found by checking the daily programs of activity for each person from the time of rising until bedtime at night. The daily programs of both executives and employees revealed almost without exception the stress of arti-

cial living. The usual program was a continuous performance mentally, physically or both, throughout the day, with meals in the same tempo as work or play, and ending with overeating at the evening meal. This program caused overfatigue and also gave rise to the habits of fast eating and eating when overtired. In the winter months undue indoor living was almost universal. With closed cars and increased indoor diversions, in many cases not more than ten or fifteen minutes a day was spent outdoors. Relatively few men took regular exercise, and when taken it was usually indoors.

The value of these accurate check-ups became apparent at once to the person examined, revealing the lack of planning his day in such manner as to obtain the essentials of health.

The most serious faulty health habits as related to hypertension were habitual overfatigue (caused by continuous performance under pressure), excessive intake of calories and faulty food habits, indoor living and lack of regular exercise, and worry and stress. Several, and frequently all, of these factors appeared in each case on analysis of the daily program. A majority of the men examined were readily convinced of their importance and were interested in undertaking their correction.

At each visit the applicant was weighed and his two day diet list checked, and every other week his blood pressure was taken. Suggestions were made for the correction of his daily program of living and his faulty health habits. Return visits were especially necessary for the overweight men, who required reeducation in food habits in order to accomplish a gradual loss in weight and at the same time to preserve a sense of well-being and comfort.

The prompt reduction in blood pressure that resulted from the correction of faulty health habits and the improvement in general health and efficiency were adequate incentive for following the program for physical fitness.

The number of visits made to the department was 1,687, an average of seventeen return visits.

RESULTS

GROUP 1.—This group consisted of the seventy-seven executives and employees.

Cases of Overweight: There were forty men with hypertension in the high mortality zone of overweight. The range of their weight was from 21 to 92 pounds (9 to 42 Kg.) above the optimum weight for height and from 37 to 111 pounds (17 to 50 Kg.) above the average weight for height.

Twenty-eight of these men followed our program and reduced their weights 252 pounds (107 Kg.), with an average loss of 9 pounds (4 Kg.). They reduced their blood pressure 548 mm., with an average reduction of 19 mm. The range of time was from one month to five years, and the average period, twenty-seven months. The average number of visits was thirty.

Twelve men showed an increase in blood pressure. Two had chronic nephritis, with a blood pressure of 194/110 and 235/115, respectively. Five did not control their diet. They increased in weight an average of 6 pounds (3 Kg.), with an average increase in blood pressure of 5 mm. Five relapsed after reducing their weight an average of 15 pounds (7 Kg.) and their blood pressure an average of 22 mm. in periods ranging from three months to three years. At the last reading these men were overweight an average of 43 pounds (19 Kg.).

Cases of Optimum Weight: There were twenty-seven cases of optimum weight. The blood pressures ranged from 144 to 195 mm. The results obtained with the men who followed the program regularly and those who

did not were as follows: Twenty men weighed in regularly, the average number of visits being ten and the average reduction in blood pressure 14 mm. Seven men weighed in irregularly, the average number of visits being four and the average reduction in blood pressure 1 mm.

Cases of Underweight: There were ten cases of underweight. The blood pressures ranged from 143 to 165 mm. In this group seven men came in regularly,

and they made an average of eight visits for periods varying from one to four years. The final check-up showed an average increase in weight of 1 pound (0.5 Kg.) and an average decrease in blood pressure of 10 mm. In five cases the pressure reached a normal level, and in another, 144 mm.

Of the remaining three men, two returned once only, their blood pressure showing an average increase of 3 mm. The third, a man of marked nervous instability, made forty visits to the department in two and one-half years. During this time his systolic pressure ranged from 215 to 165 and his diastolic pressure from 115 to 90 mm. Further medical study by his own physician was indicated, but he was not interested in having this done.

GROUP 2.—This group consisted of the twenty-three policyholders.

Cases of Overweight: Twenty-two overweight men followed the program, making an average of ten visits. They reduced their weight 152 pounds (69 Kg.), or an average of 7 pounds (3 Kg.), and their blood pressure 427 mm., or an average of 19 mm. The range of time covered was from one month to two years and the average period five months.

Cases of Optimum Weight: There was but one case of optimum weight. The blood pressure was reduced 36 mm.

Cases of Underweight: There were no cases of underweight in this group.

Summary of Results in the Two Groups.—Seventy-eight men returned regularly. The average of the initial readings of their systolic blood pressure was 160 mm. After periods of from one month to five years the average was 142 mm., a reduction of 18 mm.

The results obtained by these seventy-eight men, according to weight groups, were as follows: Fifty

overweight men were an average of 44 pounds (20 Kg.) above the averages of the table. They reduced their weight an average of 8 pounds (4 Kg.) and their blood pressure an average of 20 mm. At the final check-up they still had an average weight of 36 pounds (16 Kg.) above that of the table. Their blood pressure was an average of 2 mm. below 143. Twenty-eight men not overweight reduced their blood pressure an average of 14 mm. The average final reading was 144 mm.

Twenty-two men increased their blood pressure an average of 3 mm. The average initial reading was 162 mm. The final readings, taken after periods varying from one month to five years, showed an average of 165 mm.

The causes of failure to improve were as follows: Two men had chronic nephritis. One man had abnormal nervous instability. Five men relapsed after reducing their weight an average of 15 pounds (7 Kg.) and their blood pressure an average of 22 mm.

Five men (overweight) did not control their diet, increasing their weight an average of 6 pounds and their blood pressure an average of 5 mm.

Nine men did not return regularly because they were under the care of their own physicians or for other reasons. Their blood pressure remained the same, an average of 10 mm. above normal.

Fifty-four men reduced their blood pressure to a normal range of from 143 to 118 mm., as follows: Thirty-four reduced to an average of from 143 to 133 mm.; sixteen reduced to an average of from 133 to 123 mm., and four reduced to an average of from 123 to 118 mm.

The correlation of weight to reduction in blood pressure is shown by the following typical case:

A man aged 62, who was a "high pressure" manufacturer, complained of getting out of breath on moderate exercise, of "pounding" of his heart and of tiring easily. The physical defects were hernia (for which he wore a truss) and mal-

occlusion. His faulty health habits were continuous performance under pressure, overeating, fast eating and the candy habit. He reorganized his daily program and corrected his faulty health habits. At the end of the first three months, after he had reduced his weight 10 pounds (4 Kg.), his blood pressure returned to normal (130 mm.). He remarked, "I never realized I could feel so well as now." His final reduction was 25 pounds (11 Kg.) in weight and 28 mm. in blood pressure.

This case shows an early reduction in blood pressure out of proportion to the reduction in weight, which indicates that the subject's hypertension was due more to the excessive number of calories taken than to overweight (chart 2). A similar relation of reduction in

blood pressure to reduction in weight for twenty-seven men who weighed in every two weeks is shown in table 6.

At the end of six weeks the total reduction in blood pressure was 27 mm., with a reduction of 14 pounds (6 Kg.) in weight. It will be seen that there was a drop of 24 mm. at the end of the second week. Evidently this was due more to the correction of faulty health habits than to loss in weight.

In many cases we found that with the reduction of calories to the needs of the patient there was a reduction in blood pressure and a marked improvement in appearance and well-being although the weight remained constant. In other words, the by-products of incomplete combustion were apparently more potent in causing hypertension than weight itself.

The small number of physical defects is accounted for by the fact that practically all these men had been examined by their own physicians and many of them by specialists.

Chart 2.—Correlation of weight to reduction in blood pressure as shown by a typical case.

Except in the two cases of nephritis, physical defects were not definite causes of hypertension. Abscessed and dead teeth were removed, but reduction in blood pressure occurred before their removal. The glycosuria, enlarged prostate and sinl infection, which appeared each in one case, were mild and not definite factors. On the other hand, not one of the men was free from serious faulty health habits.

COMMENT

The physical fitness service is essentially a health service. It is based on the diagnosis and correction of causes of impaired health other than disease. The object of the physical examination is to exclude disease and to determine the state of the person examined. In every instance in which disease was found the applicant was referred to his own physician or dentist. No prescription was given or drug used. When hypertension was found it was considered a symptom of impaired health. After the correction of the causes of impaired health, we obtained the results recorded in this paper.

In a sense, all health work is medical work and therefore should be carried on by the physician. However, the details of health work are so many that a

well trained physical fitness worker is as necessary in this field as the nurse in the field of medical and surgical practice. Our physical fitness program at the home office of the Aetna Life Insurance Company is carried on by one full time physical fitness worker and one physician, who is present only two days every other week. Between 5,000 and 6,000 visits have been made to the department yearly.

We find in the literature that it is still debated whether hypertension is a disease or a symptom and that essential hypertension is considered a disease entity.

In this series of 100 cases we found only one case of questionable essential or hereditary hypertension. The patient was unwilling to have a complete medical examination made.

The majority of the men had been under the care of one and often of several physicians. The advice given ranged from reassurance that hypertension was a normal process occurring after middle life and hence not a cause for worry to the advocacy of an alarmist regimen calling for the avoidance of all excitement and the discontinuance of many, if not all, exercises and activities.

Return visits were necessary because the treatment consisted essentially of reeducation in habits of living and because the results shown by the weekly weighings and the biweekly blood pressure readings served as convincing evidence of the importance of keeping to the program.

We found the majority of the men interested in following directions when the causes of their hypertension were found and definite directions given for their correction. In fact, the number of return visits made by busy executives from distant parts of the state did not differ from the number made by executives and employees in the same building.

SUMMARY

A physical fitness service based on health diagnosis was offered a group of executives, employees and policyholders of the Aetna Life Insurance Company.

Among the first 1,020 men applying for this service there were 120 with hypertension. Of these, 100 (84 per cent) made an average of sixteen return visits to the department in their efforts to attain a higher standard of health by seeking optimum weight, by correcting their physical defects and faulty health habits and by reorganizing their daily program of living.

The average age of these men was 47 (range, from twenty-one to seventy-eight). Ninety per cent had considered their health above average, and 58 per cent had considered it optimum. Only 3 per cent considered their health below average, and none felt that it was poor.

An average of one physical defect and four faulty health habits was found.

The results obtained were as follows: Seventy-eight men returned regularly and reduced their blood pressure an average of 18 mm. This level was found at final readings taken from two months to five years after the initial readings. Twenty-two men did not lower their blood pressure, because of organic disease or failure to correct their faulty health habits.

Overweight was a cause of hypertension in forty cases, but the by-products of incomplete metabolism, caused by habitual overeating, were apparently more potent causes of hypertension than weight itself.

The chief cause of hypertension in twenty-eight cases in which it was not overweight was faulty health habits; namely, habitual overfatigue, indoor living, lack of regular exercise and faulty food habits.

No case was found of "essential" hypertension. We believe this term is a misnomer applied in cases in which no accurate diagnosis is made.

Only one man with possible "hereditary" hypertension was found. He was unwilling to have a Wassermann or other laboratory tests made.

Regular return visits were essential, as treatment consisted of a reeducation in habits of living.

The definite measure of results attained by the correction of faulty health habits, as indicated by the regular weighing and the reading of the blood pressure, was an adequate incentive for return visits.

Our experience indicates that hypertension is a symptom and is not a disease; that this symptom is caused more often by faulty health habits than by physical defects; that patients with hypertension are interested in correcting both physical defects and faulty health habits and in rearranging their daily program of living when definite directions are given them; that health diagnosis as an essential part of adequate medical diagnosis is not sufficiently stressed in modern medical practice.

Clinical Notes, Suggestions and New Instruments

RUPTURE OF THE STOMACH IN THE NEWBORN

ABRAHAM TOW, M.D., AND HENRY ROSS, M.D., NEW YORK

Rupture of the stomach in the newborn is a pathologic curiosity. Dunham and Goldstein¹ reported two cases in 1934 and in a review of the literature could find only nine others. Later in the same year Smythe² added two more. The following is an additional report, bringing the total to fourteen:

REPORT OF CASE

F., a boy, was born at term, weighing 7 pounds (3,175 Gm.). It was the mother's second pregnancy. The maternal history was irrelevant. Labor was easy and delivery was spontaneous. The infant was in good condition at birth. There was no evidence of asphyxia or trauma of any kind. He lost 2 ounces (57 Gm.) in the first twenty-four hours but regained his birth weight on the third day. At 1 p.m. of this day he suddenly became cyanotic and his breathing was labored. The abdomen was somewhat distended. Rectal irrigation temporarily lessened this distention. Normal fecal matter was obtained. On physical examination at 4 o'clock he was in a stuporous state. The rectal temperature was 101 F. Breathing was rapid and shallow. There was some spasticity of all the extremities. The throat was examined with difficulty. The abdomen was markedly distended but soft and pliable. At 8 o'clock the temperature had risen to 104.2 F. Breath sounds were more rapid and shallow and the breathing was stertorous. The infant died at 10 p.m.

Autopsy was performed by Dr. Aaron S. Price thirty-six hours after death. The body was well developed and well nourished. There was no evidence of damage to the skull. There was marked abdominal distention.

An incision was made from the sternum to the symphysis, and as soon as the abdomen was opened a large amount of foul odored gas escaped, leaving the abdomen in a relaxed state. The incision was extended downward. A diffuse exudative peritonitis was found, with a large amount of fluid

and some plastic exudate. The intestine and omentum were extremely congested. There was a large perforation in the anterior portion of the stomach along the greater curvature near the cardiac end which measured seven-eighths by one-half inch (22 by 18 mm.). The stomach was filled with coagulated curdled milk, and through the opening the gastric contents were leaking out. Microscopic examination of the stomach showed an acute exudate over the peritoneal surface with numerous bacterial deposits and some bile pigment in the exudate. There was considerable autolysis of the mucosa with extreme congestion and dilatation of its blood vessels. There was no way of positively proving the etiology of the condition found but, from the appearance of the stomach, it was believed to be an acute ulcer with perforation.

The lungs were completely atelectatic, except along the anterior margins. Microscopic examination showed atelectasis and congestion with a slight degree of hemosiderosis.

Microscopically the liver showed rather marked congestion, a slight degree of simple degenerative changes, and slight hemosiderosis. Microscopic examination of the spleen also showed an extreme degree of congestion.

Examination of the skull and brain showed no evidence of fracture, tentorial laceration or intraventricular or intracerebral hemorrhage. The rest of the examination also was negative.

COMMENT

Rupture of the stomach is usually secondary to an ulcer. Various reasons have been offered to explain the etiology of acute gastric ulcer but it seems probable that the essential cause is some interference with the blood supply to the area affected. Lack of nutrition permits the action of the gastric juice to bring about necrosis and ulceration. Embolism, thrombosis, vascular disease, direct injury to the mucosa in gavage, congestion due to asphyxia at birth and septicemia have each in turn been held responsible for the production of this vascular injury. In addition, Weiss and Mallory³ have called attention to vomiting as a cause of lacerations in the cardiac end of the stomach. It is also possible that when rupture has occurred it may be due to some congenital defect in the stomach wall. However, no such case has as yet been demonstrated.

Perforation of the intestine is more frequent than either perforation of the stomach or perforation of the duodenum, which conditions occur about equally.⁴ However, with perforation of the intestine some congenital defect is usually found distal to the site of rupture. This may be either a defect in the lumen due to intrinsic causes or a stenosis produced by a peritoneal band. In a review of the cases of gastric rupture cited previously, such a lesion was present in only one case.⁵ But this was a partial obstruction of the ileocecal valve and it is hardly likely that it bore any relation to the gastric lesion.

Perforation has occurred in all areas of the stomach—cardiac, middle, pyloric, anterior and posterior surfaces, greater and lesser curvatures. In some cases it has even occurred twice in the same patient. Diagnosis is difficult but it should be suspected in the presence of a distended abdomen with or without signs of toxemia. However, this distention is not always present. The abdomen, although swollen, may be soft and easily palpated, and the absence of rigidity, as in older patients, should not mislead the examiner. A history of hematemesis or the presence of blood in the stool is suggestive of an ulceration, but in several of the cases reported neither of these signs was present. X-ray examination by means of a flat plate may show the presence of free gas in the peritoneal cavity. Paracentesis of the abdomen should also be considered as a diagnostic aid. Treatment is surgical and the usual supportive measures administered postoperatively. The progress is not absolutely hopeless, as Davenport and Goldstein⁶ have reported recovery from a peritonitis associated with intestinal bands in an infant weighing 5½ pounds (2,500 Gm.).

Special Article

THE USE OF VITAMIN D PREPARATIONS IN THE PREVENTION AND TREATMENT OF DISEASE

EDWARDS A. PARK, M.D.

BALTIMORE

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed.

But for rickets vitamin D would not have been discovered. Its discovery was the secret to rickets; its use is essentially the therapy of that disease. The most direct way to furnish the foundation for intelligent use of vitamin D is to review briefly the sources and requirements of this factor from the point of view of practical therapeutics.

At the present time no less than ten forms of vitamin D are known,¹ but only two have practical importance. One is activated ergosterol of plant origin, in its pure form known as calciferol and given the name of viosterol by the Council on Pharmacy and Chemistry; the other is activated 7-dehydrocholesterol, of animal origin, the form of vitamin D discovered by Waddell² and the one which develops in the skin under the action of ultraviolet rays.³ The short ultraviolet rays of the sun or those derived from artificial sources (such as the quartz mercury vapor lamp and the carbon arc lamp) convert the provitamin in the skin, 7-dehydrocholesterol, into the active form. This is absorbed by the blood. If the vitamin is fed, it is absorbed from the small intestine as a result of the action of bile. In the one case the vitamin formed on the surface of the body finds entrance into the interior through the skin; in the other, ingested ready made, it is absorbed through the intestine. The result is the same.

The accepted standard unit for expressing the strength of vitamin D, as adopted by the United States Pharmacopeia, is defined as the vitamin D activity of 1 mg. of the international standard solution of irradiated ergosterol, found equal to 0.025 microgram of crystalline vitamin D. This is the international unit accepted as the U. S. P. unit, except that the U. S. P. standard is a reference cod liver oil that has been assayed against the international standard. In stating doses of antirachitic agents, one should think in terms of international units (or U. S. P. units, which are identical⁴), for that is the only way in which the various substances containing vitamin D, which differ from one another so much in bulk, can be reduced to a common denomina-

tor. One quart of irradiated milk, for example, contains 135 U. S. P. units, whereas 1 mg. of calciferol contains 400,000.

It is necessary to understand that vitamin D is present in only a few foods ordinarily eaten by us; namely, in milk and some dairy products, in liver and the flesh of certain fish and in eggs. Campion, Henry, Kon and MacKintosh⁵ have found that the milk obtained in June from cows kept outdoors contains from 17 to 26 units per quart, a very small amount, whereas the milk of cows kept indoors contains only from 5 to 8 units per quart, practically none. Bechtel and Hoppert⁶ reported the content of summer milk as 40 units per quart and of winter milk as 5 units per quart. Apparently pasture feeding has no influence on the vitamin D content of milk, but pasture life in summer does because of exposure of the cow to the sun's rays. The point to realize is that unless special means are taken to enrich the milk with the vitamin, such as feeding irradiated yeast, irradiating the milk itself or adding the vitamin directly, milk is a feeble source of vitamin D. The vitamin in milk is in the butterfat. As expected from the foregoing account, this assays at low values. Average butter is estimated as containing only 80 units per hundred grams, having only about one-hundredth the potency of cod liver oil. Mammalian liver contains from 10 to 45 units per hundred grams, again a small quantity.⁷ The content of liver is probably also extremely variable; it may be nil. Canned fish, sardines and salmon contain small amounts of vitamin D. The vitamin D of eggs is contained entirely in the yolk. Samples of yolks of February eggs have been reported to contain 140 units of vitamin D, and of June eggs 390 units per hundred grams.⁸ Although eggs, like milk, can be improved from the standpoint of vitamin D content if special means to that end are taken, the important point is that as ordinarily marketed they contain too small and at the same time too uncertain an amount of vitamin D to be counted on as a dependable source.

The Eskimos must take extremely large, at times tremendous, quantities of vitamin D in their diet, since through the exigencies of nature they eat largely fish and the fatty flesh of fish-eating animals and birds. Seal flesh is high in vitamin D.⁹ The Eskimos owe their protection from rickets and osteomalacia to their diet. Rickets makes its appearance among them as soon as our foods become substituted for theirs.¹⁰ This fact in itself is a cogent indictment of our diets for deficiency in vitamin D. By selection of vitamin D-containing foods (the flesh of certain oily fish, eggs, butter, liver) we also could obtain a moderate supply of vitamin D from food alone, but the diets which we do choose (ordinary milk, fruit, sugar, cereal grains, tubers, green vegetables and muscle meat) must furnish at most a negligible amount of the vitamins.

4. In this article, wherever units of vitamin D are mentioned, the U. S. P. XI unit is meant.

The infant whose diet consists of milk, sugars, fruit juices and cereals during the early months, to be supplemented later with green vegetables, potato, muscle meat and egg, will lack a supply of vitamin D almost entirely unless it is furnished by the summer sun's rays or some specially provided alimentary source.

THE ARMAMENTARIUM FOR THE CORRECTION OF VITAMIN D DEFICIENCY

I shall not discuss the relationship of ultraviolet light to vitamin D activation or the treatment of vitamin D deficiency with ultraviolet light. These subjects are dealt with in a separate section by Ethel Luce-Clausen. Instead I shall list the preparations available for the prevention and treatment of vitamin D deficiency by way of the alimentary tract, at the same time giving information of a useful, practical nature about each.

Cod Liver Oil.—The U. S. Pharmacopeia XI requires that cod liver oil shall contain not less than 85 units per gram. As a matter of fact, probably most cod liver oil marketed in this country contains at least 100 units per gram and some of the superior brands two and even four times this official standard. One teaspoonful of cod liver oil, about 4 Gm., supplies about 340 units if the vitamin is U. S. P. minimum standard strength, or about 400 units if the oil is slightly more potent. The vitamin in cod liver oil is probably chiefly activated 7-dehydrocholesterol, the same as the one which is formed in the skin through irradiation.

Cod liver oil is the time-honored remedy for the cure of rickets. Its use goes back into the middle ages.¹¹ Its advantages are: It is extremely effective in the treatment of rickets (osteomalacia), as was pointed out so clearly years ago by Trousseau;¹² it is universally available; despite assertions to the contrary,¹³ it is safe;¹⁴ it contains vitamin A in abundance (about 1,000 units per gram), and its fat is a valuable addition to the diet of many infants. The disadvantages are its lack of concentration, which makes the dose requirement large, and its fishy taste.

It is not practical to attempt to give more than 4 teaspoonfuls, about 1,600 units, daily. Cod liver oil is therefore not potent enough—not enough can be given—to prevent or cure rickets in some premature babies and in especially susceptible full term infants and older children. It is not the best remedy to stop rickets quickly. If more units of vitamin D are required than can easily be given in cod liver oil, it is necessary to turn to the concentrated preparations of vitamin D.

The fishy taste of cod liver oil virtually precludes its use in the case of the older child and adult. Most infants, however, will take it well and may even develop a liking for it if its administration is begun early and it is given regularly. If it is not given until toward the end of the first year or if its use is allowed to lapse, difficulties in administration will arise. When an infant refuses cod liver oil the trouble usually lies with the mother, who transfers her feelings and prejudices. The ease and success with which cod liver

oil may be given to children over 2 years of age when the force of example is brought into play, as in nursery schools, bear witness to the influence of the attitude of adults. One of the obstacles to the use of cod liver oil in the lay mind is the deep-rooted belief that it causes digestive disturbances, especially in hot weather, and that some infants are constitutionally unable to take it at all. Cod liver oil rarely gives rise to digestive disturbances and can be administered in hot weather without any difficulty. However, it must be admitted that some infants cannot take it. In rare instances hypersensitiveness to it may exist.¹⁵ If aspirated it may produce lipoid pneumonia. On account of this danger as well as on account of its low potency other more concentrated forms of vitamin D are to be preferred for premature infants.

Cod liver oil may be given directly from the spoon. It may, however, be floated on orange juice and the two fed together. As much as three teaspoonfuls can be given as a single dose. If the infant does not readily take it, it is wise to turn to some other preparation of vitamin D.

Viosterol in Oil.—Viosterol in oil is ergosterol activated by irradiation or by other methods and dissolved in corn oil or some other bland oil. The United States Pharmacopeia requires that 1 Gm. of viosterol in oil shall contain "at least 10,000 units." In order to prescribe viosterol in oil, it is necessary to know that the vitamin D content of 1 drop is 166 units. There are variations in the quantity of oil delivered by droppers because of variations in the droppers themselves. The manufacturer tries to compensate for these variations by using droppers which will deliver slightly more than the certified amount. Consequently the dose may slightly exceed the calculations. Viosterol in oil is prepared in such a way that it is a hundred times stronger in vitamin D content than standard cod liver oil. Its concentration is a great practical advantage but makes overdoses possible.

Viosterol in oil is tasteless; no difficulty is ever encountered in administering it. In experienced hands it is best dropped directly into the mouth. If difficulty is met, it can be dropped on orange juice in a teaspoon and floated into the mouth. It should never be added to the feeding, lest a part be lost by adhering to the sides of the bottle.

The disadvantage of viosterol, as compared with the fish liver oils, is that it does not supply vitamin A. Viosterol is well adapted for the use of older children and adults.

Before leaving the subject of viosterol it is well to point out that it is now manufactured in two different ways, one by means of ultraviolet irradiation, the other by bombardment with low velocity electrons. Viosterol made by the latter process seems to be the same chemically and biologically as the product of irradiation.¹⁶

Viosterol (Calciferol) in Propylene Glycol.—This preparation is alleged to be pure vitamin D, prepared from irradiated ergosterol, dissolved in propylene glycol. Its distinctiveness lies in the solvent employed. Because of the solubility of propylene glycol in water,

it can be mixed directly with milk. The customary procedure is to drop the dose into the milk. The disadvantage of the preparation is that it does not contain vitamin A. It is standardized so that its potency corresponds exactly with that of viosterol in oil.

Fish Liver Oils Enriched with Viosterol or Some Natural Source of Vitamin D.—To halibut liver oil, which is far richer than cod liver oil in vitamin A but only a few times more potent in D, viosterol or some fish liver oil highly concentrated in D is added in the amount necessary to raise the vitamin D concentration to equal that of viosterol in oil. The object is to obtain a preparation which is concentrated in A as well as D. If viosterol is used as the reinforcing agent, practically the entire D content of the product is viosterol. The vitamin A content of halibut liver oil varies but is standardized at about 50,000 units per gram. The administration should be like that of viosterol in oil.

Fish Liver Oils Highly Concentrated in Vitamin D.—Oils from the livers of different species of fish vary greatly in concentration of both vitamin D and vitamin A. Some are rich in A, some in D and some in both. The suborder of fish highest in vitamin D is the percomorphi.^{16b} The blue fin tuna heads this group, with the enormous concentration of 40,000 units per gram. What the manufacturers have done in the preparation of these concentrated products is to combine oils from different species in such a way that the final admixture will have the same concentration as viosterol in oil; namely, 10,000 units of vitamin D per gram (1 drop contains 166 units). Percomorph oil is standardized at about 60,000 units of vitamin A per gram, a hundred times the concentration of standard cod liver oil. These fish liver oils have the merit, therefore, of providing D and A in high concentration so that the two can be administered together in doses measured in drops. Naturally the taste is fishy, but the quantity required is very small. Administration should be like that of viosterol in oil.

Irradiated Cholesterol.—This is obtained by the irradiation of cholesterol. The form of vitamin D is activated 7-dehydrocholesterol. Its efficiency in the treatment of rickets has been investigated by Tisdall, Drake and Brown,¹⁷ Hood and Ravitch¹⁸ and, more recently, by Drake, Tisdall and Brown¹⁹ and found to be excellent.

Miscellaneous Preparations Whose Vitamin D Is Derived from the Fish Liver Oils or Viosterol.—Cod liver oil concentrate is marketed in liquid, capsule or tablet form. Concentrates from the fish liver oils are combined with carotene. Viosterol is furnished in combination with dicalcium phosphate and similar compounds. The dose varies with the preparation as indicated by the label.

Vitamin D Milk.—Milk is the staple ingredient of the diet of the infant and the chief source of calories. The great advantage of placing vitamin D in milk is that it is taken willy-nilly. The disadvantage is that the amount of milk supplying the desired number of calories may not at the same time supply the full vitamin D requirement, which seems to vary with age

(growth) rather than with weight.²⁰ There are three kinds of vitamin D milk.²¹

Irradiated vitamin D milk is produced through the exposure of milk in a thin film for a brief period to the active rays of ultraviolet light from artificial sources. The milk is standardized at 135 units per quart, although some products contain as much as 200 units per quart, as indicated on the label. The potency of ordinary irradiated milk, which is obviously low, cannot be increased greatly by irradiation without the production of an unpleasant taste. The form of vitamin D produced in milk by irradiation is probably activated 7-dehydrocholesterol, as already stated. Irradiated milk is marketed fresh and also in evaporated and dried form. The latter forms are standardized so as to contain 135 units to the reconstituted quart.

Metabolized vitamin D milk is produced by feeding irradiated yeast to the cow. It is standardized so as to contain not less than 400 units per quart. Its potency in rat units is thus approximately three times that of irradiated milk. The form of vitamin D is irradiated ergosterol, which apparently passes through the cow into the milk unchanged.²²

Fortified vitamin D milk is produced through the direct addition of a vitamin D-containing concentrate derived from cod liver oil, other fish liver oils, viosterol or fish liver oil emulsions. It is standardized at 400 units per quart. The form of vitamin D in the milk varies naturally with the form in the supplement.

In the case of each of the three varieties the taste is not impaired by the enrichment process, so that the milk is a hidden source of vitamin D and the problem of administration, whether to old or young, is merely that of administration of the milk itself.

Vitamin D Bread.—Bread has been produced containing 460 units in the form of viosterol to the 24 ounce loaf. Six slices would yield about 115 units.

RELATIVE VALUES OF DIFFERENT FORMS OF VITAMIN D

In 1930 the surprising observation was made that viosterol was far less effective, rat unit for rat unit, in curing leg weakness in chickens than was cod liver oil. This observation at once suggested that the two might have different degrees of effectiveness in the human being as well. Quickly investigating this lead, Hess, Lewis and Rivkin²³ reported that the activity of cod

20. For example, in the study of L. T. Davidson, K. K. Merritt and S. S. Chipman (Prophylaxis of Rickets in Infants with Irradiated Evaporated Milk, *Am. J. Dis. Child.* 53: 1 [Jan.] 1937) in which prevention of rickets was attempted by the use of irradiated milk alone, the average intake of milk for the full term infants at the age of 1 month was 396 cc. This amount of milk yielded only 57 units of vitamin D. At the age of 6 months the increased amount of milk taken supplied 114 units. In the case of the premature infants the average amount of milk taken at 1 month was 284 cc. The vitamin supplied by this quantity was only 41 units daily! At 6 months the vitamin D supplied had risen to 103 units daily. The need for vitamin D is greatest during the first four months of life, but during this period the intake of milk was so small that the vitamin D requirement was not met.

21. For the methods of preparation and standardization of these varieties of activated milk the following references are available: Becker, J. E., and Conn, L.: How the Potency of Vitamin D Milk is Determined, Ninth Annual Report, New York Association of Dairy and Milk Inspectors, 1935, p. 153. Shrader, J. H.: Fortification of Milk with Vitamin D, *Arch. Phys. Therapy* 15: 709 (Dec.) 1934. Krauss, W. E., and Bethke, R. 23. Hess, A. F.; Lewis, J. M., and Rivkin, Helen: Newer Aspects of the Therapeutics of Viosterol (Irradiated Ergosterol), *J. A. M. A.* 94: 1885 (June 14) 1930.

liver oil and that of viosterol for the human being were actually different, 1 rat unit of cod liver oil accomplishing the work of 4 of viosterol. In 1931 Hess, Lewis, MacLeod and Thomas²⁴ reported further that yeast milk, rat unit for rat unit, was more effective in the human being than cod liver oil or viosterol, the efficiency equivalences being in order of 1:1.25:5.2, respectively. In 1933 Hess and Lewis²⁵ published evidence that for the human being irradiated milk was even more potent than yeast milk when the two were compared with viosterol. These studies were upsetting: Did the infant stand somewhere between the rat and the chicken in relationship to the two forms of vitamin D? Was vitamin D dispersed in milk superior to vitamin D dispersed in oil?

At least thirty-nine studies have been made in this country and in Canada which bear on these questions. Out of the conflicting and most confusing results only generalizations of a tentative nature are possible.²⁶ For practical purposes the vitamin D in viosterol may be regarded as being equal to the vitamin D of cod liver oil. If viosterol is inferior to cod liver oil, rat unit for rat unit, and it very likely is, the difference cannot be great or it would have come out more clearly. Vitamin D is more effective dispersed in milk than dissolved in the usual oil menstrums. Milk enriched with vitamin D in the three different ways may be regarded from the practical point of view, rat unit for rat unit, as having equal value. But evidence suggests that the vitamin D, unit for unit, in irradiated milk may be superior to that in metabolized milk. Vitamin D milk having a potency of 400 units per quart will supply enough vitamin D to meet the requirements of the majority of full term infants. On the other hand, it seems fairly clear that irradiated milk has too low a potency (135 units per quart) to be relied on for this purpose. Four hundred units of vitamin D per quart of milk may be regarded as the minimum concentration in that menstrum to be relied on for protection of the infant. This subject has been discussed in great detail by Jeans.²⁷ In regard to vitamin D in the oil menstrums, the situation is too confused to permit even tentative judgment. It is suggested that, in the case of the fish liver oils and viosterol, for working purposes from 800 to 1,000 units be regarded as the lowest level which it is wise to employ for the infant.

25. Hess, A. F., and Lewis, J. M.: An Appraisal of Antirachitics in Terms of Rat and Clinical Units, *J. A. M. A.* **101**: 181 (July 15) 1933.

26. The problem is beset with great practical difficulties. The tests must be made on infants, but infants are available, relatively speaking, only in small numbers and some must be set aside for control purposes. Furthermore, infants are not uniform test subjects. They vary in age, diet, racial stock and individual constitution. The diagnosis of rickets and treatment cannot be relied on to carry out the treatment.

The study of each child must last for weeks (curative) or months (preventive), but the season when the study can be carried out without great liability to error is limited to five months. To make matters still more difficult, the available criteria for the detection of rickets in its early stages are not entirely satisfactory. The early clinical signs of rickets are notoriously deceiving and cannot be relied on. When the rickets becomes advanced, the x-rays furnish an accurate means of recognition, but in the early stages of the disease their use is attended by error of unknown, but probably considerable, magnitude. Finally, the substances to be compared number at least four, which has caused subdivision into groups so small that results are meaningless. Although the complexities of the problem offer excuse, a considerable proportion of the studies made have been badly thought out or carelessly done or carried out on too small or too heterogeneous a collection of infants to make the results significant. In a number of instances the methods of procedure employed have precluded a comparison of the results with those of other studies. I am inclined to agree with Jeans that the hope of solution of the problems involved lies in carefully conducted inpatient studies in which the diet and environmental conditions can be controlled and the really accurate methods of measuring vitamin D deficiency (measurements of the calcium and inorganic phosphorus in the blood serum and of the calcium and phosphorus balance) can be employed, but there have been few of these.

27. Jeans, P. C.: Vitamin D Milk: The Relative Value of Different Varieties of Vitamin D Milk for Infants; A Critical Interpretative Review, *J. A. M. A.* **106**: 2066 (June 13), 2150 (June 20) 1936.

It is a fortunate circumstance in deciding on doses of vitamin D that exact knowledge concerning the lower levels of requirement is not necessary because there is at present no reason to believe that amounts of vitamin D well above the minimum levels have any deleterious influence. The rule which the physician should follow in prescribing vitamin D is to administer it in ample enough quantity to cover any possible requirement.

THE PREVENTION OF RICKETS AND INFANTILE TETANY IN THE AVERAGE CASE

The Use of Vitamin D in Oils.—The period of greatest susceptibility to rickets is the first months of life. Whatever antirachitic substance is employed, it is important that full doses be reached early, certainly during the second month. Cod liver oil is taken as a paradigm. In my opinion its administration should be started at the beginning of the third or fourth week, with a dose of one-half teaspoonful (200 units); after two or three days this should be increased to 1 teaspoonful, so that at the end of the third or fourth week the dose is about 400 units. During the fourth or fifth week the dose is raised to 2 teaspoonfuls (about 800 units). According to circumstances this level may be allowed to stand or may be raised during the second month to 3 teaspoonfuls (1,200 units) daily. There is no possible objection to giving 1,200 units of cod liver oil daily if it is well taken and borne. Indeed it is advisable to give this dose if reason exists for thinking the infant particularly liable to rickets. The dose of from 800 to 1,200 units should be given throughout the first year. Eight hundred units should be given throughout the second year.

In most instances difficulties in administration do not occur during the first year but usually do arise some time during the second. When this happens it is advisable to turn to one of the concentrated fish liver oils, viosterol in oil or milk activated with vitamin D.

Cod liver oil, like liquid petrolatum, causes lipid pneumonia²⁸ if it runs down the larynx into the lungs or is aspirated after vomiting. It should not be used, therefore, if vomiting occurs frequently. As already pointed out, it should not be given to premature infants if concentrated preparations are available.

The question is often asked whether the use of cod liver oil should be continued during the summer, since the need is less then on account of the wealth of ultraviolet light in the sun's rays at that season. Theoretically, if the infant is well exposed to the summer sun's rays daily, the dose of cod liver oil (or other antirachitic preparation) can be reduced or the administration stopped altogether. Practically, it is good policy to continue through the summer, because interruption often breaks down habit on the part of mother as well as child and makes resumption difficult or impossible. If cod liver oil is under suspicion as the cause of digestive disturbances or is distasteful, it is best to substitute some other preparation of vitamin D.

If it is decided to use a concentrated vitamin D preparation, such as one of the fish liver oils, a fish liver oil enriched with viosterol, viosterol in oil or irradiated cholesterol, the procedure is the same as that outlined; namely, to begin in the third or fourth week and increase the dose rapidly to 800 units. Depending on circumstances, the dose may remain the same or it may be increased to 1,200 units daily. The dose should be

28. Goodwin, T. C.: Lipoid Cell Pneumonia, *Am. J. Dis. Child.* **48**: 309 (Aug.) 1934.

maintained for the first two years as described under the heading "Cod Liver Oil." The mode of administration has already been described.

The Use of the Different Forms of Vitamin D Milk.—If milk is employed as the vehicle for vitamin D, the quantity given must always be chosen by the caloric, never by the vitamin D, need. If the quantity is insufficient to supply the vitamin D need, it should be supplemented with vitamin D from some other source. As already indicated, metabolized vitamin D milk and fortified vitamin D milk are potent enough to be relied on to prevent the development of rickets in the majority of full term infants. It is wise, however, especially if the infant is not under close supervision, to supplement with one of the oils containing vitamin D during the first six months. Four hundred units of the oil preparation should be given, beginning at the third or fourth week of life. If irradiated milk with its low unitage is employed, it must certainly be liberally supplemented with some other preparation of vitamin D throughout the first year.

PREVENTIVE MEASURES FOR ESPECIALLY SUSCEPTIBLE INFANTS

For the protection of premature infants and those who are peculiarly susceptible to rickets, the different forms of vitamin D milk may prove insufficient. No reason exists why they should not be used, but liberal supplementation with preparations highly concentrated in vitamin D is imperative. The best course is to treat the infant as if the activated milk did not supply any vitamin D at all. To premature infants it may be necessary to give 1,000, 5,000 or 10,000 units or for a time even more daily in the form of the highly concentrated fish liver oils, viosterol in oil or other vitamin D preparation. In the case of especially susceptible full term infants and older children it is sometimes necessary to exceed 30,000 units daily. The physician discovers that the case is one of special requirement only when the ordinary preventive treatment proves insufficient. The course then is to increase the dose until an adequate therapeutic level is reached. It is wise to allow three weeks to elapse between increases in doses, because that length of time is needed for effects to become fully evident. When an increase becomes indicated it should be made boldly; i.e., from 5,000 to 10,000 units should be given. How to watch in order to make sure that the dose is holding the rachitic tendency in check is discussed later.

HOW TO CURE RICKETS

Amounts of vitamin D which will prevent rickets in a given case will always cure the disease, but often too slowly. If rickets exists, it is best to use large enough doses of vitamin D to end the disease rapidly. When the disease is under control the doses can be lowered. The vitamin D milks are not potent enough to meet the emergency of the cure of rickets, and cod liver oil itself must be abandoned occasionally for this reason.

If cod liver oil is again taken as a paradigm, the curative dose in the ordinary case is 1,200 units (12 Gm., or three teaspoonfuls) daily. This dose in the form of cod liver oil or the highly concentrated fish liver oils and viosterol preparations is sufficient to bring advanced rickets under control within three weeks in the great majority of cases. If larger doses of vitamin D are required, as happens occasionally, it is best to

use the concentrated forms of vitamin D. Sometimes, particularly in the case of premature infants, one is forced to give daily from 10,000 to 20,000 units or occasionally even more in order to bring the disease to a complete termination, and in the case of some older children one may be obliged to raise the dose to 60,000 units daily or even to exceed that amount (see treatment of refractory rickets). When the rickets has been stopped, as ordinarily happens in a month's time, the dose of vitamin D can be tapered off to lower levels but often not to the low preventive levels which serve for the average infant. In the case of some children in whom the tendency to rickets is obstinate, large doses of vitamin D may be required indefinitely. In the case of premature infants the need of large doses is usually temporary.

HOW TO TREAT INFANTILE TETANY WITH VITAMIN D

The same rules apply to the vitamin D treatment of infantile tetany as apply to the treatment of rickets with this exception, that during the first days calcium in some form should be administered with the vitamin. The explanation for this advice is that the initial action of vitamin D in some cases is to cause a depression of the serum calcium content at the same time that it causes an elevation in the level of the inorganic phosphorus. The lowering of the serum calcium excites an outbreak of the tetany. This possibility is avoided if calcium is given simultaneously. If calcium chloride is employed it is advisable to administer from 3 to 4 Gm. as an initial dose, followed by 1 Gm. four times a day for two or three days and then 1 Gm. twice a day. The administration of calcium can usually be stopped entirely at the end of a week or ten days, but the vitamin D treatment should be continued.

VITAMIN D IN THE TREATMENT OF REFRACTORY RICKETS

The physician may occasionally encounter a child with rickets which will not yield to vitamin D, even in large doses. Refractory rickets is most often discovered in children above 3 years of age (late rickets). The survival of the rickets into the age period when it ordinarily dies out means either that extraordinarily bad environmental and dietetic conditions keep the disease alive or else that some not understood peculiarity in the child exists which renders the lime salt-depositing mechanism insensitive to the presence of vitamin D. The manifestations, clinical, x-ray, serologic and metabolic, are essentially the same as those in the ordinary infantile form. The diagnosis of refractory rickets must be made by trial and failure of vitamin D therapy. The therapeutic secret in some cases, as discovered through the audacity of Albright, Butler and Bloomberg,²⁹ is to increase the dose of vitamin D until an effect is produced. In their case (that of a boy of 16 years whose rickets had persisted from infancy in spite of the various orthodox therapeutic procedures) it was necessary to increase the dose to between 1,000,000 and 1,500,000 units daily before healing was induced! Now to maintain the normal state, Albright³⁰ states, it is necessary to give 150,000 units daily. In a similar case, that of a 7 year old child, presently to be reported by Guild and Wilkins, it has been necessary to raise the dose to 300,000 units daily to make calcifi-

29. Albright, Fuller; Butler, A. M., and Bloomberg, Esther: Rickets Resistant to Vitamin D Therapy, *Am. J. Dis. Child.* 54: 529 (Sept.) 1937.

30. Albright, Fuller: Personal communication to the author.

cation of the skeleton complete. In both cases proof was established that the fault was not failure to absorb vitamin D from the alimentary tract. Probably instances are extremely rare in which such enormous doses of vitamin D are required. Most cases of refractory rickets of the kind under discussion will yield to the administration of 50,000 or 60,000 units daily.

Before the physician concludes that the condition before him is refractory rickets, he must ascertain, first, that it is not the fairly infrequent disease renal hyperparathyroidism (renal osteitis fibrosa, renal rickets; see Park and Eliot³¹ for points in differential diagnosis), which is not influenced favorably by vitamin D therapy, and, second, that it is not one of the rare, recently discovered varieties of endogenous rickets, which are by-products of obscure metabolic disturbance and not dependent at all on vitamin D deficiency or cured by vitamin D administration. Instances of endogenous rickets have been described by de Toni,³² Fanconi,³³ Debré, Marie, Cléret and Messimy³⁴ and Schier and Stern³⁵ and probable instances by Ullrich³⁶ and Schlesinger.³⁷ The characteristic features are glycosuria with a low blood sugar content (renal diabetes), acidosis due to the presence of an unidentified organic acid, retardation in physical development (dwarfism) and rickets of an osteoporotic type, which may be extreme. Particularly if glycosuria is found, attention should be directed to the possibility that the condition belongs in this curious category.

Probably another form of rickets of endogenous origin has been described by Kaufmann³⁸ and by Lignac.³⁹ Disturbance in cystine metabolism, giving rise to cystinuria, and retardation of growth are characteristic features.

In this connection I must call attention also to reports of refractory rickets in which success in treatment was thought to depend on the administration of alkali.⁴⁰ In Bornscheuer's case improvement is said to have occurred when the vitamin D treatment was stopped and the patient placed on a diet yielding a large excess of base. In Boyd's case and in that of Stearns and Warweg the rickets treated with vitamin D yielded on the additional administration of sodium bicarbonate.

Finally I would call attention to the fact that in obstructive jaundice vitamin D is not absorbed well from the alimentary tract. Heymann⁴¹ has recently brought forward additional experimental evidence that the bile is essential for the absorption of vitamin D.

Under the title "Rachitis Hepatica," Gerstenberger⁴² reported two cases of rickets in infants suffering from congenital obliteration of the bile ducts. He considered the rickets refractory to vitamin D. In all probability the disease was ordinary infantile rickets due to failure in absorption of the small quantities of vitamin D administered.⁴³

THE PRODUCTION OF RAPID HEALING

Occasionally it is important to effect a rapid cure of rickets. For example, in "thoracic rickets," described by Park and Howland,⁴⁴ the weakness of the thorax menaces life. Under such circumstances it is incumbent on the physician to supply rigidity to the thoracic bellows as quickly as possible. In the case of a baby aged 8 months suffering from advanced rickets, one can give daily doses of 50,000 units of vitamin D. When the healing begins, as can be detected by means of roentgenograms or determinations of the calcium and inorganic phosphorus, the dose should be reduced. Harnapp,⁴⁵ Bischoff,⁴⁶ and Schirmer⁴⁷ have given infants single doses of 600,000 units without bad effect. After a single dose the vitamin probably remains in the body for a number of weeks.⁴⁸ I do not recommend the single dose method. The diet should contain ample calcium and phosphorus.

HOW TO GAGE THE SUCCESS OF VITAMIN D THERAPY

One can assume that preventive treatment is succeeding if the signs of rickets do not make their appearance in the roentgenogram of the radius and ulna and—provided the infant is full term—if the level of the calcium of the serum remains above 9 mg. and that of the inorganic phosphorus above 5 mg. per hundred cubic centimeters. Rickets can develop in the premature baby even though the levels of calcium and inorganic phosphorus are within the range accepted as normal (calcium 10 mg. and inorganic phosphorus 5 mg. per hundred cubic centimeters of blood). Periodic estimations, at monthly or two-monthly intervals, of the calcium and inorganic phosphorus in the blood serum and x-ray examinations are the most reliable means of determining that rickets is not developing. However, for all practical purposes one can be sufficiently certain that the preventive treatment is successful if clinical evidences of rickets do not make their appearance.

If the problem is one of cure, the condition ordinary rickets and the dose of vitamin D about 1,200 units, the first indication of therapeutic effect will be a rise in the level of inorganic phosphorus in the serum. This begins about ten days after treatment has been begun. About three weeks after the beginning of treatment the shadows of fresh deposits of lime salts make their appearance in the roentgenogram, often in the form of a transverse line, usually broken, crossing the transparent cartilage just beyond the end of the shaft. As

48. Metabolism and Mode of Action of Vitamin D: D in Different Tissues in Vivo, *J. Biol. Chem.*

treatment continues, this line of deposits becomes thicker and more dense. Finally the gap between it and the end of the shaft becomes completely filled with lime salts. The filling in process may take two months. The pattern of the rickets may last for a very long time after the disease has completely stopped.

This is the ordinary course of events, but if larger doses of vitamin D are given the changes in the blood and the roentgenograms can be more rapid. For example, after very large single doses of vitamin D Harnapp,^{45b} Bischoff⁴⁶ and Schirmer⁴⁷ reported rises in the serum calcium and phosphorus content and signs of fresh depositions of lime salts in the roentgenograms as early as the fifth day.

It is difficult to be sure of the healing effect of treatment from clinical examination alone, for recession of the deformities is gradual. Perhaps the most obvious clinical indication of successful treatment is the improvement in muscular function. The child begins to make efforts to walk or to sit up. He seems stronger and more active.

If the treatment is adequate the improvement will be steadily progressive; if inadequate, either no improvement or improvement which presently stops will occur.

VITAMIN D IN THE TREATMENT OF OTHER CONDITIONS

The use of vitamin D has been extended to a variety of diseases far removed from rickets. Apparently the basis of its use for some of the diseases has been the belief that its toxic effects are beneficial. The justification is entirely empiric.

I mention the diseases in question and give references to the literature but cannot pass judgment. I remark merely that the evidence offered in favor of the therapeutics in some instances seems rather slim.

Rappaport and Reed⁴⁹ have reported favorable effects from massive doses of vitamin D for hay fever; Dreyer and Reed,⁵⁰ Wyatt, Hicks and Thompson,⁵¹ Livingston,⁵² Vrtiak and Lang⁵³ and Farley,⁵⁴ for chronic arthritis. The dose ranged from 200,000 to 1,000,000 units (in one instance) given daily over periods of weeks or months. Toomey⁵⁵ has suggested vitamin D therapy as a possible means of increasing resistance to infantile paralysis. Krafka⁵⁶ and more recently Ceder and Zon⁵⁷ (the latter authors used massive doses) have reported striking effects in psoriasis. Weld⁵⁸ has reported favorable action in increased capillary permeability, and McNealy, Shapiro and Melnick⁵⁹ and Johnston,⁶⁰ in checking of the bleed-

ing tendency in cases of obstructive jaundice. Richardson⁶¹ stated that vitamin D given during pregnancy may reduce the duration of labor and the loss of blood. Theobald⁶² has found it useful in treating the toxemia of pregnancy.

EVIDENCE THAT DOSE IS EXCESSIVE

The idea that vitamin D in the form of irradiated ergosterol is an extremely toxic substance was derived from the use of the old German preparation vigantol, in the wake of which metastatic calcification was observed by a variety of investigators.⁶³

In the treatment of chronic arthritis and psoriasis enormous doses of vitamin D have been employed. From these experiences, which have been limited to adults, it is possible to obtain an idea of the symptoms produced by overdoses. Wyatt, Hicks and Thompson,⁵¹ who limited the dose to 300,000 units daily, reported in one case violent persistent nausea, intense headache and profuse sweating and in another severe diarrhea, loss of appetite and slight headache. Vrtiak and Lang⁵³ used from 150,000 to 250,000 units daily over periods of months. They reported that in all their patients nausea developed and in some nocturia and frequent micturition. Farley,⁵⁴ who in most instances administered 200,000 units but in cases of obstinate arthritis increased the dose to 300,000, 600,000 units and even (in one case) 1,000,000 units daily, noted nausea and increased micturition. He stated that toxic symptoms seldom developed if the dose remained under 400,000 units. In Guild and Wilkins' 7 year old child with refractory rickets receiving 300,000 units, the symptoms indicating that the proper dose had been exceeded were loss of appetite, pallor and lassitude.

In contrast to the indefinite evidence afforded by the symptoms enumerated, clear indications of an overdose may be found in the urine and in the calcium and the inorganic phosphorus level of the blood.

If the dose is high the physician should examine the urine daily, looking in particular for calcium casts, such as Albright and Bloomberg⁶⁴ have described in cases of hyperparathyroidism (they will not be found if the urine is sufficiently acid). He should also keep close track of the level of the calcium and the inorganic phosphorus in the blood serum and if rickets is present of depositions of lime salts at the ends of the radius and ulna as revealed in roentgenograms. How often he should examine the blood and have roentgenograms taken depends on the size of the dose and the age and size of the child. If extremely large doses, for example 100,000 units or more, are given, examinations of the blood ought to be made at weekly or, in critical situations, at semiweekly intervals. X-ray examinations of the bones should be made at weekly or biweekly intervals. Elevation of the serum calcium above 12 mg. per hundred cubic centimeters is the great danger signal.⁶⁵ In Ceder and Zon's⁵⁷ carefully watched patients (adults receiving 300,000 units) the serum

65. Albright, Butler and Bloomberg²² wrote: "The calcium content of the serum rose to 12.7 mg. and the phosphorus content to 3.5 mg., and the phosphatase content fell to 13.5 Bodansky units per hundred cubic centimeters. This increase in the serum calcium and phosphorus was fortunately noted at once, so the dose was lowered and was eventually stopped for a short time. At the height of the rise in the blood values the urine was loaded with calcium and contained many calcium casts such as have been observed in cases of hyperparathyroidism."

calcium rose to levels varying from 12 to 16 mg. per hundred cubic centimeters. With the rise in the serum calcium a rise in inorganic phosphorus takes place, but if rickets is present this may not reach even the normal level. If the excessive vitamin D therapy is persisted in, undoubtedly the inorganic phosphorus level as well as the calcium level will become much elevated and metastatic calcification will occur, as is regularly the case in animals subjected to toxic doses of vitamin D.⁶⁶ The rule holds that the dose of vitamin D will not become toxic so long as the calcium and inorganic phosphorus levels in the blood are not affected. Apparently toxic action does not depend on the level of vitamin D in the blood but rather on its effects on the calcium and phosphorus metabolism. For example, in Guild's case of refractory rickets (previously referred to) the concentration of vitamin D in the blood rose to 200 times the normal before signs of an overdose showed themselves. If rickets exists, great aid is furnished by roentgenograms alone. If the film reveals shadows which indicate healing, one knows at once that the vitamin has begun to act and that the calcium and phosphorus levels have been affected. The signs of healing in the roentgenogram do not mean that the dose of vitamin D should be lowered, but they inform the physician that the hoped for healing has begun and place him at once on his guard against toxicity.

The physician should be on his guard for signs of toxicity in the child if the daily dose exceeds 50,000 units. If the patient is a very small infant, e.g., a premature infant, the physician should watch with care even if the dose is 20,000 or 30,000 units. Toxic manifestations will not occur immediately but only after a period of two or three weeks and need not be expected so long as the rickets, if this condition is present, remains unaffected. With the adult the physician ought to exercise great caution in venturing into the unknown with daily doses of 200,000 units or more.

VITAMIN D AND THE TEETH

It is certain that rickets causes enamel hypoplasia.⁶⁷ This condition can be prevented by the prevention of rickets. Evidence is accumulating that administration of vitamin D during childhood, particularly in the early years, reduces the incidence of dental caries.⁶⁸ The permanent teeth are in process of development from birth during the entire period of growth. The possible influence of vitamin D in the protection of the teeth from hypoplastic deformities and caries is a sufficient reason for the continuation of the vitamin D therapy throughout child life.

THE VITAMIN D REQUIREMENT AFTER THE SECOND YEAR

The reason usually given to explain the particular susceptibility of the infant to rickets is rapid growth, but this explanation really has no meaning. The older child is occasionally subject to rickets ("late rickets"), but the adult never has osteomalacia (rickets after growth has ended) unless under extreme provocative conditions. It is not understood why the child and

adult are so insusceptible. The adult rat is far more resistant to rickets-producing diets than the young animal, but even the young rat does not appear to need vitamin D if the diet is perfectly constituted. If, however, deficiencies in the calcium and phosphorus are sufficiently great, vitamin D may exert a striking rectifying effect. It is easy to demonstrate the protecting influence of vitamin D on the skeleton of the pregnant rat. These experiences can probably be carried over in principle to the human adult and to the older child. If the diet is excellent—this includes the supply of calcium and phosphorus—either no vitamin D is required or a very small quantity suffices. If, on the other hand, the supply of calcium and phosphorus is at fault, vitamin D will exert a helpful influence.

A large proportion of children and adults must receive a modicum of vitamin D in their food. This modicum, which would be totally inadequate for the infant, may be significant for the adult because of his small requirement. The facts in this regard simply are not known. On the other hand, great numbers of people receive no vitamin D or virtually none from their food. A large proportion of children and adults must obtain liberal supplies of vitamin D from exposure to the sun in the summer, late spring and early fall months, when the active ultraviolet rays are in abundance and this vitamin is probably stored for weeks in the body.⁴⁸ Others, particularly those confined indoors or to the hearts of cities, derive little or no vitamin D from this source. Moreover, large groups of persons are denied the sun's rays the year round because of their occupations, e.g., miners, night workers and indoor workers in general, or because of personal habits or necessities (invalids). These are the facts.

In the case of the child the physician should be certain that the administration of vitamin D is not stopped at the end of the second year. It is undoubtedly more important for the child to receive it during the third than during the fourth year and during the fourth than during the fifth. The need of the child for the vitamin probably declines with increasing age. Nevertheless I recommend that it be given throughout the growing period. A sufficient reason for this advice is the possibility that the administration of the vitamin may aid in improving the durability of the teeth.

In the case of the adult the course is not so clear. Probably in most cases in which a physician has the opportunity to advise, the patient does not require vitamin D from an additional source and would not feel different or actually be in better health if he received it. On the other hand, in many instances the patient would probably be benefited, perhaps greatly, by receiving it. It seems a sound policy to advise vitamin D for (1) all patients who by force of circumstances are deprived of the opportunity of obtaining the vitamin from the sun (night workers, factory workers and persons confined indoors, in particular invalids), (2) for all persons whose diet is lacking in milk, the sole valuable source of calcium, or is generally poor, (3) for the aged, particularly when they are limited as to diet and confined indoors, (4) for persons suffering from fractures or having had operations on bones and (5) for all pregnant women, no matter what the diet or the season. With regard to pregnancy, evidence which cannot be disregarded exists that vitamin D is a safeguard both to mother and to infant. The physician should unfailingly see that every woman during pregnancy receives vitamin D.

66. Shelling, D. H., and Asher, Dorothy E.: Calcium and Phosphorus Studies: IV. The Relation of Calcium and Phosphorus of the Diet to the Toxicity of Viosterol, *Bull. Johns Hopkins Hosp.* 50: 318 (May) 1932.

68. Agnew, M. C.; Agnew, R. C., and Tisdall, F. F.: The Production and Prevention of Dental Caries, *J. Am. Dent. A.* 20: 193 (Feb.) 1933. Committee for the Investigation of Dental Disease: The Influence of Diet on Caries in Children's Teeth, Medical Research Council, Special Report Series No. 211, London, His Majesty's Stationery Office, 1936.

I want to point out that it would be of undoubted benefit if the habit of taking vitamin D in some form were universal. If our food were like that of the Eskimo, with vitamin D a regular ingredient, rickets would disappear almost entirely, the state of the teeth might undergo improvement and the level of health of many persons might be raised. I believe that the physician ought to extend the use of vitamin D wherever he is able, in particular during the winter months, even if he is unable to measure benefit in individual cases.

As for the preparation of vitamin adapted for the adult and child, cod liver oil is not especially suitable, but the other sources are, the vitamin D milks, the preparations of viosterol in oil and the highly concentrated fish liver oils. For the pregnant woman I suggest a daily dose of 800 units and for the child a dose of from 300 to 400 units. I presume that for the average adult a dose of 135 units daily, such as would be supplied by a quart of irradiated milk or six slices of vitamin D bread, would be more than ample, but I have no means of even guessing what the amount should be.

Before leaving this subject I wish to make two practical comments. First, since the adequacy of all diets in vitamin A for older children and adults has not been satisfactorily established, I suggest that the preparations which combine A and D be chosen in preference to those which contain D alone. Vitamins A and D go together (fat-soluble) and may well be administered together. The concentrated fish liver oils, which are rich in vitamin A as well as D, are to be preferred to the viosterol group for this reason. Second, since older children and adults often take very little milk, fortified and metabolized vitamin D milks are to be preferred as sources of vitamin D to irradiated milk. One glass of irradiated milk, which is as much milk as many adults take in a day, would yield only 67 units of vitamin D. In the light of the previous comment, fortified milk is superior if the addition of the fish liver oil concentrate increases the content of vitamin A as well as that of vitamin D.

RELATIVE COST OF THE DIFFERENT PREPARATIONS OF VITAMIN D

The only reasonable way to compute the relative values of the different preparations of vitamin D is per unit of the contained vitamin. On this basis cod liver oil is the cheapest. It is interesting that some of the cod liver oils having the higher unitage, though costing more per volume, are actually the most economical. For example, at a local inquiry it was found that the cod liver oil with the highest unitage (350 units per gram) sold at 90 cents a pint; its calculated cost per 1,500 units was eight tenths of a cent. Oil selling at 50 cents a pint and having only the required 85 units per gram cost twice as much per 1,500 units, namely, 1.9 cents. The oils depending on viosterol for their enrichment in vitamin D and viosterol itself cost in general twice as much as the concentrated fish liver oils. The fish liver oils highly concentrated in vitamin D are as economical sources as many of the poorer brands of cod liver oil. From the standpoint of unitage, irradiated milk is about one third as potent as metabolized or reinforced milk. In the case of each of the vitamin D milks the enrichment process usually adds 1 cent a quart, although some dairies have not increased the price and vitamin D evaporated milk sells at the same price as ordinary evaporated milk.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
PAUL NICHOLAS LEECH, Secretary.

THE COUNCIL ACCEPTS FOR INCLUSION IN N. N. R. SOME PRODUCTS OF THE UPJOHN COMPANY

Until now no product of the Upjohn Company has been accepted by the Council on Pharmacy and Chemistry because of conflicts with the rules of the Council. Under date of Dec. 17, 1937, the firm informed the Council that it wished to work in harmony with the aims and rules of the Council. The firm has demonstrated its willingness to remove certain causes of conflict and has in general shown a commendable desire to meet the requirements of the Council. After considerable correspondence and negotiation, the Council voted to remove application of Rule 11 and to consider products submitted on the basis of their individual merits. Notices of acceptance will appear in the usual manner in the N. N. R. column of THE JOURNAL.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

PHENOBARBITAL (See New and Nonofficial Remedies, 1938, p. 123).

PHENOBARBITAL-THE UPJOHN COMPANY.—A brand of phenobarbital-U. S. P.

Phenobarbital Tablets, ¼ grain: Supplied in both white and green tablets.

Prepared by The Upjohn Company, Kalamazoo, Mich.

Phenobarbital Tablets, ½ grain: Supplied in both white and green tablets.

Prepared by The Upjohn Company, Kalamazoo, Mich.

Phenobarbital Tablets, 1½ grains: Supplied in both white and green tablets.

Prepared by The Upjohn Company, Kalamazoo, Mich.

STAPHYLOCOCCUS VACCINE (See New and Nonofficial Remedies, 1938, p. 427).

The Upjohn Company, Kalamazoo, Mich.

Staphylococcus Mixed Vaccine.—A suspension of strains of *Staphylococcus aureus* and *albus* in physiological solution of sodium chloride preserved with 0.5 per cent phenol, containing 1,000 million killed organisms of *Staphylococcus aureus* and 1,000 million killed organisms of *Staphylococcus albus* to each cubic centimeter. Marketed in packages of six 1 cc. ampules and 5 cc. and 20 cc. vials.

**BACTERIAL VACCINE MADE FROM THE
TYPHOID BACILLUS** (See New and Nonofficial Remedies, 1938, p. 429).

The Gilliland Laboratories, Inc., Marietta, Pa.

Typhoid Vaccine.—Also marketed in vials of 50 cc. containing 1,000 million killed typhoid bacilli per cubic centimeter.

The Upjohn Company, Kalamazoo, Mich.

Typhoid Vaccine.—Marketed in packages of three 1 cc. ampules, one containing 500 million and two containing 1,000 million killed typhoid bacilli each suspended in physiological solution of sodium chloride and preserved with 0.5 per cent phenol.

**BACTERIAL VACCINE MADE FROM THE
TYPHOID BACILLUS AND THE PARATYPHOID
"A" AND "B" BACILLI** (See New and Nonofficial Remedies, 1938, p. 431).

Lederle Laboratories, Inc., Pearl River, N. Y.

Typhoid Combined Vaccine (Prophylactic).—Also marketed in packages of one 20 cc. vial containing 1,000 million killed typhoid bacilli, 500 million killed paratyphoid A bacilli and 500 million killed paratyphoid B bacilli per cubic centimeter.

The Upjohn Company, Kalamazoo, Mich.

Typhoid Paratyphoid Mixed Vaccine.—A suspension in physiological solution of sodium chloride preserved with 0.5 per cent phenol. Marketed in packages of three 1 cc. ampules, one ampule containing 500 million killed typhoid bacilli and 375 million each of killed paratyphoid A and paratyphoid B bacilli, and two ampules each containing 1,000 million killed typhoid bacilli and 750 million each of killed paratyphoid A and paratyphoid B bacilli. Also marketed in 5 cc. and 20 cc. vials containing in each cubic centimeter 1,000 million killed typhoid bacilli and 750 million each of killed paratyphoid A and paratyphoid B bacilli.

SATURDAY, SEPTEMBER 24, 1938

HOUSE OF DELEGATES CONSIDERS NATIONAL HEALTH PROGRAM

The third special session of the House of Delegates in the history of the American Medical Association convened in Chicago September 16, called especially to consider the National Health Program and other matters proposed by the Board of Trustees. On two previous occasions, once when our country was at war and the services of the American Medical Association were required to aid the government in meeting the war needs for medical service, and again when the Social Security Act was before Congress, the House of Delegates met in special session. Following the National Health Conference, government officials indicated that the proposals there made would be drafted into legislation which would be brought before the next Congress. The Board of Trustees called the House of Delegates so that it might establish the policies of the Association specifically with regard to these proposals. Those who read the proposals, which were published in THE JOURNAL July 30, realize that the National Health Program is truly an attempt to chart the proposed expansion of medical and public health activities in the United States during the next ten years. The House of Delegates (see the complete minutes, this issue, page 1191) considered most carefully not only the proposals of the National Health Program but also many plans and proposals from county and state medical societies and from various individuals.

Briefly, the House of Delegates recommended expansion of public health services, as related to the control of certain infectious diseases, maternal and infant welfare, and similar projects, with the definite understanding that the need be established and that they be efficiently handled and economically controlled. The House of Delegates approved the principle of hospital insurance, again with the understanding that it cover only the facilities of the hospital and that professional standards be maintained. It approved the principle of *cash indemnity insurance* for meeting sickness costs, provided these efforts meet the requirements of state laws and that they have the approval of the county and

state medical societies under which they operate. The House of Delegates again recognized the need for complete medical services to the indigent, at the same time emphasizing the desirability of local control. The House recognized that the necessity for state aid might arise in poorer communities and that the federal government might need to provide funds when the state is unable to meet these emergencies. The needs of the medically indigent were considered, and a definition of medical indigence was supplied. Here the House felt that the determination must be made locally as to the group covered by this term, that control of the service should lie with local administration, and that available facilities should be utilized before new facilities were provided. Thus, the House of Delegates felt that there was but little need for the building of new hospitals or the establishment of new diagnostic centers, provided better utilization of hospitals and laboratories already functioning can be devised.

Again the House of Delegates stated its firm opposition to any compulsory sickness insurance plan. Finally, it approved protection against loss of income during illness.

The members of the American Medical Association will do well to read, if not even to learn, the principles established by the House of Delegates. Every member should do all that he can to inform the public concerning these actions. The Association has not abandoned any of its policies for the maintenance of professional standards. It has, however, again recognized the importance of securing wider distribution of medical service.

The Board of Trustees presented to the House of Delegates the statement concerning the proposed investigation by the Department of Justice, which seeks to obtain an indictment of the American Medical Association as a monopoly. The statement has been made repeatedly that the American Medical Association is ready for investigation by any authorized agency, firmly reliant in the belief that its actions are in accordance with its constitutional organization, that they have been taken in the interest of the public health and welfare, and that it has never violated the established laws of this country. The House of Delegates expressed its firm conviction in the truth of these statements and urged the Board of Trustees to oppose with its utmost power, even to the courts of last resort, this apparent attempt to convict the American Medical Association in the eyes of the people of being a predatory, antisocial monopoly.

In this connection, one of the most dramatic phases of the recent meeting of the House of Delegates was the appearance of three representatives of the National Medical Association, an organization of more than 5,000 Negro physicians, who indicated that overtures had been made to them by government officials, with a view to inducing that organization to put its ambitions

in the hands of the government. Notwithstanding these overtures, the National Medical Association, through its committee, expressed a wish to go forward with the American Medical Association as members of a great profession for the public service.

The meeting of the House of Delegates had a most wholesome effect in allaying doubts and fears among the medical profession as to the position of the American Medical Association in relationship to recent propaganda that has been widely circulated in this country. The unanimity of expression and action again indicated that these representatives of 110,000 American physicians are able as a democratic body to express the wishes of the vast majority of the medical profession in this country and to speak with one voice for them.

CHANGING POPULATIONS: THE INFERENCES

In an editorial published last week entitled "Changing Populations: The Premise"¹ the latest estimate of probable trends in population as outlined in a recent government monograph² was partially analyzed. If correctly anticipated there will be a great change in the age distribution of the population by 1980. According to the hypotheses of low fertility, medium mortality and no immigration there will be in 1980 only about 6½ million under 5 years of age (12,143,000 in 1930), 21½ million between 5 and 20, 44½ million between 20 and 45, nearly 40 million between 45 and 65, and 22 million over 65 (6½ million in 1930). Assuming a medium fertility and medium mortality, there would be more in the younger age groups than in the first hypothesis, 9,906,000, for example, under 5 years of age. With immigration there would be a still slightly higher proportion in the younger age groups. Under any of these hypotheses there would be an increased proportion of elderly (dependents) and a lowered proportion of children (dependents), both factors of economic and social importance. If any of these forecasts prove correct, and there are valid reasons to believe that at least some will, the effects on the nation's fundamental economy will be profound and will require considerable adjustment. It may not, however, be assumed that the results will all be deleterious. While the implications are too numerous to be listed at this time, some of the changes to be expected are of particular interest to the medical profession.

Obviously, if correct, more medical care will be required for the elderly and the adult and less for children. This should be considered in the training of physicians as well as in the provision of hospitals, sanatoriums and homes for old persons. In providing these facilities, adequate recognition of differential

birth rates and future population centers is of integral importance. The types of illness to be expected are of equal importance: with only occasional exceptions it would seem foolish to build many hospitals for contagious diseases of children or institutions devoted to cholera and typhoid; conversely, sanatoriums for old persons and institutions for the care of arthritic patients would seem more in keeping with probable demand.

In the section of the report dealing with health and physical development appear several valuable suggestions together with others which the medical profession will consider an unwarranted distortion of the facts. Many of the factual data are taken bodily from the report of the Committee on the Costs of Medical Care, notwithstanding that some of these figures have been seriously questioned. The report calls attention to the extraordinary advance in the expectation of life—a record attributable largely to the efforts of preventive and curative medicine—to improvements in child health, and to progress in the control of typhoid, tuberculosis and industrial accidents. In spite of the progress which has been made, the deficiencies are emphasized—as indeed they should be—and the extraordinary burden of mental defect and disease, the blind, the crippled and the degenerative diseases are discussed.

Because of the greater life expectancy in New Zealand, mentioned in the previous editorial, that country is selected as a model to be emulated and the inference is drawn that one of the principal reasons for the longer life expectancy is the "more adequate provisions for making medical services generally available to the whole population in that country." However this may be, New Zealand is in the throes of complete reorganization of its "more adequate provisions."³ It is pointed out that South Dakota and Kansas most closely approximate the life span of New Zealand and that the "more favorable health conditions prevailing in New Zealand may be attributed in part to conditions comparable to those prevailing in our Northwestern states" as well as to the available medical services. This is perhaps an egregious example of unreasonable inference—no real account is taken of all the possible contributory factors such as relative rural and urban distribution, climate, race, heredity, occupation, economic status, comparability of medical care and innumerable other factors. The implied conclusion that medical services supplied as in New Zealand would increase the life span in this country to the level of that country is unwarranted by the evidence submitted.

Whatever the deficiencies in basic assumption or inference contained in this report on the problems of a changing population, it constitutes in its entirety a contribution of great credit to its compilers and the most authoritative statement of probabilities on the subject available today.

Current Comment

NEW FILMS ON PHYSICAL THERAPY

To stress the importance of physical therapy as an adjunct to the practice of medicine and surgery, the Council on Physical Therapy is utilizing motion pictures as an educational medium. These deal with the value of simple measures such as heat, light, massage and therapeutic exercise, including underwater movements. Apparently one reason why physical therapy has not been accorded more widespread acceptance on the part of the general practitioner is its close association, in his mind, with "machine therapy." This unfortunate connotation has disturbed physicians in some localities. While it is true that the machine is a useful adjunct to the practice of medicine in certain instances, at least 90 per cent of the good accomplished by physical therapy results from the use of simple measures. The new films prepared recently and now available for loan to those wishing them for educational purposes include:

Aids in Muscle Training: This film replaces an old one entitled *Simple Measures Facilitating Graduated Active Motion*. In addition to the subjects which were previously considered, such as sling suspension exercises for the upper and lower extremities, graded exercises on a powdered board are shown for the lower extremities. This film also demonstrates three kinds of "walkers" for reeducation exercises.

Occupational Therapy: This film replaces the old one of the same title. It shows occupations that may be prescribed by physicians to motivate and control the desired physical or mental activity of the patient and assist in his adjustment to long hospitalization. A section on cerebral palsy is included, picturing indirect muscle training through prescribed activity and stressing the importance of early treatment to prevent growth of faulty habit patterns.

Underwater Exercises: This is a new film presenting the therapeutic use of large and small exercise pools, Hubbard tanks and home-made tanks and showing types of exercises given in cases such as infantile paralysis, cerebral palsy and postoperative congenital dislocation of the hip.

Massage: This film replaces one which was formerly used to demonstrate the technic of massage, describing the various movements and why they are performed in a given way.

Contraction of Arteries and Arteriovenous Anastomoses: This film visualizes the contraction of arteries and arteriovenous anastomoses as seen through a glass chamber installed in a rabbit's ear.

The Council has had several films for loan which have been shown in the past before state, county and local medical societies. Because of their popularity they have become too worn for further projection. However, duplicates have now been made which are in excellent condition. The titles follow:

Effects of Heat and Cold on Circulation of Blood: This film shows the effect of heat and cold on circulation as seen through a glass chamber installed in a rabbit's ear.

Effects of Massage on Circulation of the Blood: Similar to the foregoing except that it shows the effects of massage.

In addition, two old films are still available on the following subjects:

Therapeutic Exercises for the Shoulder Joint Following Dislocation: This film demonstrates static, passive, active and resistive exercises for the shoulder joint, including work with pulley and weight.

Treatment of Compression Fracture of the First Lumbar Vertebra.

The films may be procured by writing to the Director of Exhibits of the American Medical Association. An advance request will insure the film being reserved for the desired date.

CONGENITAL INSENSITIVENESS TO PAIN

A peculiar insensitiveness to pain in three children has been reported by Ford and Wilkins.¹ One, a boy of 9, sustained numerous injuries including fractures, extensive burns and a laceration of the cornea without apparent painful reaction. This child had a normal intelligence and a mild congenital word blindness. The child's behavior and physical and laboratory tests were essentially normal. Another, a boy of 8½, appeared equally insensitive to burns and other injuries. His neurologic examination was negative but his intelligence quotient was only 76. He demonstrated various behavior disorders and had a bad family background and a long history of minor illnesses. He had always been emotional and subject to night terrors and temper tantrums. The third, a girl aged 7, was found insensitive to potentially painful stimuli over the entire surface of the body, although she was not indifferent to pain of visceral origin; neurologic examination gave negative results and the mental age was low normal. In discussing the cases the authors pointed out that the nature of this peculiarity is not clear. All three children could distinguish between the sharp and blunt ends of a pin and could recognize slight differences in the temperature of test tubes. Although it might be suggested that these children are analgesic and distinguish between the point and end of a pin by means of tactile sensibility, Ford and Wilkins do not find it possible to accept this theory since patients with true analgesia, such as in syringomyelia, cannot make such a differentiation. They believe, therefore, that these patients do not have analgesia or loss of any type of sensibility but that they are merely indifferent to pain and that these facts do not necessarily indicate a true dissociation between pain of peripheral and of visceral origin. Furthermore, this unusual reaction cannot be considered due to mental defect nor, in the cases in question, does hysteria seem to offer an acceptable explanation. They are also unable to accept the explanation of certain psychoanalysts that insensitiveness to pain of this type may be the expression of a sadomasochistic personality. This indifference to pain, they believe, is apparently of congenital origin, for in all three cases the peculiar reaction of the children to injuries was discovered before they had reached the age of 3 years. In association with information obtained from the literature, therefore, Ford and Wilkins are inclined to believe that these cases represent a congenitally defective development in the sensory system which involves selectively the pain mechanisms and is comparable to congenital color blindness and similar conditions.

ORGANIZATION SECTION

PROCEEDINGS OF THE SPECIAL SESSION

MINUTES OF THE SPECIAL SESSION OF THE HOUSE OF DELEGATES OF THE
AMERICAN MEDICAL ASSOCIATION, HELD AT CHICAGO, SEPTEMBER 16-17, 1938

HOUSE OF DELEGATES

First Meeting—Friday Morning, September 16

The House of Delegates convened in the Red Lacquer Room of the Palmer House and was called to order at 10:25 a. m. by the Speaker, Dr. H. H. Shoulders.

Preliminary Report of Reference Committee on Credentials

The Speaker appointed the following Reference Committee on Credentials:

Deering G. Smith, Chairman.....	New Hampshire
Raymond L. Zech.....	Washington
James R. McVay.....	Missouri
William H. Myers.....	Georgia
William R. Molony Sr.....	California

Dr. Deering G. Smith, Chairman, stated that one hundred delegates had filed proper credentials.

He moved the approval of seating regularly elected delegates who had been unable to be present at San Francisco but whose alternate delegates had attended that session and of seating alternate delegates with proper credentials in place of regularly elected delegates who had been present at the San Francisco session but who were not present at this session. The motion was seconded by Dr. A. T. McCormack, Kentucky, and carried.

On motions of Dr. Smith, duly seconded and carried, the following physicians were seated as delegates in place of delegates who served at the San Francisco session: Dr. W. W. King, Colorado, in place of Dr. John W. Ames, Colorado, and Dr. John Andrew, Colorado, in place of Dr. Harold T. Low, Colorado.

It was moved by Dr. Smith, seconded by Dr. H. B. Everett, Tennessee, and carried, that the delegates thus far seated constitute the roll of the House.

Call for the Special Session

The Secretary read the following call for the Special Session of the House of Delegates, which he stated had been sent to each member of the House of Delegates of the San Francisco Session 1938, in accordance with the specific provisions of the By-Laws:

To the Members of the House of Delegates of the American Medical Association:

In compliance with the official request of members of the Board of Trustees that the House of Delegates be convened in special session, I, as Speaker, under authority of chapter III, section 2, of the By-Laws hereby officially call the House of Delegates of the American Medical Association to convene in special session in the city of Chicago, state of Illinois, at 10 a. m., daylight saving time, on the 16th day of September 1938.

The business to be transacted at this special session shall be limited to the consideration of the national health program submitted to the National Health Conference recently held in Washington and to such other matters as may be submitted to the House of Delegates by the Board of Trustees.

The House shall remain in session, recessing from day to day, until its deliberations are concluded.

This call is issued August 26, 1938.

H. H. SHOULDERS, M.D.,
Speaker, House of Delegates,
American Medical Association.

Representatives of National Medical Association

The Vice Speaker, Dr. R. W. Fouts, took the Chair.

The Secretary stated that Drs. Roscoe C. Giles, Clarence H. Payne and Carl G. Roberts, all of Chicago, were accredited representatives of the National Medical Association, a national organization of colored physicians, dentists and pharmacists in the United States, to confer with the House of Delegates and with officers and members of the American Medical Association at this special session; that these physicians had appeared before the Board of Trustees at its meeting on September 15, and that he had promised to let them know whether the House of Delegates would permit them to sit in as observers during the session.

It was moved by Dr. A. T. McCormack, Kentucky, seconded by Dr. George W. Kosmak, New York, and carried after discussion, that Drs. Giles, Payne and Roberts be invited to attend the meetings of the special session of the House of Delegates as observers and that they be permitted to address the House on request of the Speaker.

Address of the Speaker, Dr. H. H. Shoulders

The Speaker, Dr. H. H. Shoulders, read his address, which was referred to the Reference Committee on Reports of Officers and Board of Trustees.

Members of the House of Delegates:

It is customary for the House of Delegates to hear an address by the Speaker of the House, the President and the President-Elect. That precedent will not be broken in this extraordinary session unless there is objection.

As your new Speaker, presiding for the first time under these extraordinary conditions, I wish to request the display of an attitude of tolerance on the part of the membership toward my shortcomings.

It may be appropriate to draw attention to this gavel. It was made from wood grown at the Hermitage home of Andrew Jackson. It was presented to me by the medical profession of Nashville, Tenn. There is a legend to the effect that it endows the recipient with some of the attributes of Old Hickory. You will remember that he used a gavel and a gun with equal facility and effectiveness when the proper occasion arose.

As I said to the House last June, my conception of this House of Delegates is that it is the only representative group of medical men in the United States in position to speak for the whole profession of medicine and every point of view within the profession. This is the forum to which every medical problem may be brought with the full assurance that it will receive consideration.

Doubtless each member of the House has an opinion and maybe a conviction on each of the various issues which may be considered at this session of the House. It is reasonable to expect these opinions to conflict to some extent when we think of the wide variations in the local problems presented in the various communities throughout the country.

It is my observation that the House has always displayed an attitude of tolerance toward those who hold views contrary to our own. We have displayed something of the sentiment expressed by Voltaire, "I wholly disapprove of what you say but will defend with my life your right to say it."

The display of such a spirit on this occasion will contribute much toward the end that the actions taken by the House on the issues presented will deserve and receive the respect of the profession and the public of the United States.

I have participated with you in the deliberations of this House for a number of years. We are all familiar with the fact that a campaign has been going on for a number of years to create sentiment in favor of some radical changes in medical practice. At times this campaign has had the appearance of a "smeared" campaign. Our attitude and our motives have in many instances been misunderstood or maligned.

This House of Delegates is the policy making body of the Association. All the policies of this Association are our responsibility. We could not now, if we wished, dodge a responsibility to the profession of medicine as a whole and to the sick people of the United States. The executive officers of the Association could do no less than support these policies with vigor on all occasions.

In 1936 the campaign for some radical changes in medical practice began to take on a more definite form. An article published in the *Forum* and *Century Magazine* entitled "Medicine's Horse and Buggy" said, among other things: Today, with Thomas Parran Jr. as surgeon general and Josephine Roche as the Treasury Department's secretary for health, we may confidently expect continued pressure both from within and from without the government toward the reorganization of the health services. The accuracy of that prediction became apparent as time went on.

A little over a year later (October 1937) Miss Josephine Roche made an address before a special session of the American Public Health Association entitled "Medical Care as a Public Health Function." This address served to indicate very definitely the direction in which the radical change is to take place if she and her collaborators prescribe the form of change. In effect, she proposed that individual medical care become a function of health departments.

You, of course, are familiar with the report of the Interdepartmental Committee, which was released last February and which was designed to show deficiencies in medical care but none of its efficiencies. Finally the climax of this series of events was reached in July of 1938, when the proposals of the Interdepartmental Committee were submitted to the Health Conference at Washington.

This House of Delegates has never displayed an attitude of opposition to study and experimentation with plans for the financing of medical care by individuals or by the government. To the contrary, the House adopted principles, ten in number, to which all plans should conform. This action was not in opposition to plans and proposals. They were adopted because we believe they are essential to good medical care. We have opposed the adoption and operation of plans which do not conform to those principles.

Any one who reads these ten principles fairly will recognize the fact that they were written in the interest of patients, not in the interest of doctors. They were adopted in the interest of preserving a high order of ethical principles in the delivery of medical care to sick people under any and all plans. They were intended to restrain those who might allow their greed to ensnare them into the adoption of principles in conflict with them.

We have never taken action in opposition to government aid to the needy, whether the need was for food, clothing, shelter or medical attention.

We have opposed the administration of these benefits, and especially medical benefits, on a basis that would do violence to our whole idea of democracy.

We have opposed legislation which would have the effect of vesting in some governmental agency the power to enforce its decrees on patients and doctors.

We have never opposed provisions in any regulation or statute to protect the government and taxpayers against fraud on the part of any one.

We have been mindful of a philosophy we learned early in our professional career, to the effect that "everything that is potent for good is also potent for evil." It applies to morphine, to ether and to surgical procedures; in fact, it applies to every therapeutic measure at our command. We recognize also that the same philosophy applies with equal aptness to legislative proposals aimed at some political sociologic or economic ill.

This House of Delegates has not assumed to answer for the taxpayers of the United States the question as to whether or

not they wish to assume the financial burden of financing the complete and adequate medical care of all indigent persons as a governmental function. Nor should we assume the responsibility for answering that question now. The answer rests with the people of this country. If they should answer it in the affirmative, it will be our duty to accept the responsibility for drafting the plans. We can do no less. Our training and experience would not allow us to shirk such a responsibility even if we were so disposed.

Our knowledge of this question of medical care is the product of long years of effort and experience at the bedside of the afflicted and at the operating table. It is not limited to a knowledge gained from a brief study of a few statistical tables of doubtful accuracy. We are, and always have been, mindful of life. We are mindful also of the attributes which give flavor and purpose to living.

We remember the fact that human nature is just about the same as it was two thousand years ago. It has the same virtues and faults; the same generosity and the same greed; the same loves and hates; the same hopes and the same fears.

Our vision must see through all these conflicting attributes of human nature and with thoughts tempered with a high sense of justice and charity find a way that will lead us out of these troubled times to happier days.

Address of President Irvin Abell

The Speaker resumed the Chair and presented the President, Dr. Irvin Abell, Louisville, Ky., who delivered the following address, which was referred to the Reference Committee on Reports of Officers and Board of Trustees:

Mr. Speaker and Members of the House of Delegates:

Article 2 of the Constitution of the American Medical Association reads as follows:

The objects of the Association are to promote the science and art of medicine and the betterment of public health.

Section I, Chapter I, of the *Principles of Medical Ethics* reads as follows:

A profession has for its prime object the service it can render to humanity: reward or financial gain should be a subordinate consideration. The practice of medicine is a profession. In choosing this profession, an individual assumes an obligation to conduct himself in accord with its ideals.

In these times of changing trends in social thought it is still well to adhere to those age-old principles as guiding lights in our efforts to furnish the American people with the best medical service obtainable. At the time of their adoption, the form of society as a whole was comparatively a simple one: its evolution through the years has developed it into an exceedingly complex organization, involving changes in character of practice and in distribution of service. During these years the medical profession has sought constantly to advance its standards in every direction that promotes efficiency and operates for the increased welfare of the people we serve. Drastic changes have been made in medical education, affording assurance that the graduate of today is competent and efficient; hospitals have been improved, insuring dispensation of service compatible with modern medical knowledge; the fields of specialization have been clarified and special training delineated for those desiring to register therein. The responsibility for the advancement of medical lore rests solely on the profession; its chief capital investment is represented by the constantly accumulating body of knowledge stored in the minds, ideals, traditions and publications of its members, which is shared freely with the public through universities, journals, discussions, the public press, radio and individual consultations. This capital cannot be monopolized for profit; it does not fit into the capitalistic concept of economics, yet it is the most valuable asset we possess. The principles of ethics by which we have been governed since the organization of the American Medical Association have been criticized as being obsolescent and antiquated. It is readily admitted that its underlying principles are ancient, but it is submitted that they are the only ones, whether in the ethics and economics of medicine or industry, that have stood the test of time. The medical profession by principle and tradition is committed to the idea that the prime object, the

standard of value and the social reason for its existence are all one thing—the service it can render humanity. That service is further interpreted as the maintenance of health and the postponement of death. Whatever plan is proposed with regard to medical care is automatically tested and accepted or rejected by the profession in relation to its influence on the morbidity and mortality of the community or communities affected.

I beg your indulgence in thus briefly reviewing some of the fundamental, altruistic principles of the American Medical Association before proceeding to the matters pertinent to this special session of the House of Delegates.

PURPOSE OF THE SPECIAL SESSION

Following the passage of the Social Security Act, the President appointed an interdepartmental committee to coordinate health and welfare activities in order that the full benefits of the federal program under the act's provision may reach with minimum delay and maximum effectiveness the women, men and children for whose purpose the program was brought into existence. As you are aware, Miss Josephine Roche, chairman of this committee, announced in May 1938 that a conference would be called in Washington to consider a national health program which had been developed by a subcommittee known as the Technical Committee on Medical Care. Miss Roche was invited to attend the annual session of the House of Delegates held in San Francisco in June but found it impossible to do so. You heard her message, which was read to the House of Delegates and which is incorporated in the proceedings of the San Francisco session.

In accordance with the instruction of the House of Delegates, some of the members and officers of the Association attended the National Health Conference and had opportunity to express your point of view. Those in attendance included your president, Dr. Irvin Abell of Louisville, Ky.; your Secretary, Dr. Olin West; the chairman of the Committee on Medical Care, Dr. William F. Braasch of Rochester, Minn.; the chairman of the Committee on Scientific Assembly, Dr. James E. Paullin; the chairman of the Council on Industrial Health, Dr. Stanley J. Seeger; the Chairman of the Board of Trustees, Dr. Arthur W. Booth; the Editor of THE JOURNAL, Dr. Morris Fishbein, and several presidents and secretaries of state societies. The newspapers and periodicals have reflected to some extent the attitudes of those who were in attendance at that conference. The members included physicians and representatives of correlated professions, who were in a distinct minority; numbers of representatives of labor organizations, mutual aid and welfare organizations, farm bureaus and federations, publicists chiefly associated with liberal and radical periodicals, leading workers in the field of the hospital and of hospital insurance organizations, and governmental employees.

The Board of Trustees will no doubt present to you an outline of the National Health Program which was presented to the National Health Conference. It is for you to consider the various aspects of this program and to determine to what extent the American Medical Association shall endorse or oppose the various phases of the plans proposed. Bear in mind that the National Health Conference did not itself come to any definite conclusions. The program was set forth and largely supported by representatives of various governmental departments. Many of the lay members in attendance gave unqualified endorsement to the program as a whole or in part. Representatives of the American Medical Association, however, were unanimous in stating that they had no authority to take action on any part of the program or on the program as a whole; rather, that this was a function of the House of Delegates, the representative body of the American Medical Association, and that at a later date this program would be submitted to the House for its consideration.

During the National Health Conference no attempt was made to elicit, nor was opportunity given for, the presentation of alternative programs or for detailed discussion of all or any part of the program. If there was any single proposal on which all of those present seemed to be in agreement, it concerned the demand for a cabinet position on health and medical service under which all of the health and medical services of the government might be united. As our govern-

ment is now constituted, appropriations to put into effect various parts of the program may affect legislation involving half a dozen or more federal bureaus.

NEED FOR WIDER DISSEMINATION OF ACCOMPLISHMENTS

The medical profession of the United States faces a situation which is unique. Without calling the organized medical profession, or any considerable representation among those engaged in practice, into conference, a vast plan affecting health and medical care has been proposed to the people. In the forwarding of this plan, forces of propaganda have apparently made a studied effort to indicate that the American Medical Association opposes all change and that it is essentially a stand-pat organization. There would seem to be need at this time for a wider dissemination of the truth as to what has been accomplished by the American Medical Association for the people of this country and as to its true attitude toward the changes that are occurring in and that are being proposed for the medical care of our people.

POLICIES OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association has constantly recognized the need for continued expansion of preventive medicine and a wider use of medical care. It has, however, at the same time been greatly concerned with the methods of administering both preventive medicine and medical care and with the ultimate effect of various changes on the morale as well as on the health of our people. The charge which is sometimes made, and which was made by radical speakers during the Health Conference, that physicians oppose changes because of a desire for more and more money, is an outrageous misstatement of our attitude. It is a fundamental tenet of the American Medical Association that the poverty of a patient should demand the gratuitous services of a physician; but endowed institutions and organizations for mutual benefit or for accident, sickness and life insurance or for analogous purposes have no claim on physicians for unremunerated services. As a professional man the individual physician has a right to determine the conditions of his service.

It is a fundamental tenet of the American Medical Association that it is unprofessional for a physician to dispose of his services under conditions that make it impossible for him to render adequate service to his patient, because to do this would be detrimental to the public. It is established as a principle of our organization that it is unprofessional for a physician to dispose of his professional attainments or service to any lay body, organization or group or individual, by whatever name or however organized, under terms or conditions which permit a direct profit from the fees, salary or compensation received to accrue to the lay body or individual employing him. Such a procedure has been established as beneath the dignity of professional practice, as unfair competition with the profession at large, as harmful alike to the profession and the welfare of the public and as against sound public policy.

EXPERIMENTATION WITH NEW FORMS OF PRACTICE

Within these fundamental tenets, experimentation in new forms of medical practice has not been inhibited. Hundreds of experiments have been carried on in the past and are now being carried on under the auspices of medical societies which are component parts of this organization, planned distinctly with a view to securing a wider distribution of medical service and to making more and more medical care available to a greater number of people. Thus the American Medical Association has never opposed the principle of group hospital insurance, notwithstanding repeated attempts by those who would place the Association at a disadvantage in asserting that this House of Delegates has opposed this principle. The American Medical Association, through its component societies, has frequently given aid to the development of group hospital insurance, asking only proper safeguards for the patient and for his physician in the development of such plans.

CARE OF THE INDIGENT

The Association has never opposed suitable care by municipal, county, state or other governmental agencies for the indigent or for those on the borderline of indigence. It has

urged state, county and other medical societies to develop "the most accurate and complete information that will enable them to maintain continuous medical care that is sufficient in amount and satisfactory in quality."

STATE INTERFERENCE WITH MEDICAL PRACTICE

The Association has constantly opposed the adoption of any form of state medicine by any definition of that term and it has refused to endorse vague plans that would make the care of the indigent and of those on the borderline of indigence, or those well able to pay, a burden on the workers of this country. The American Medical Association has never opposed suitable participation by the government through any of its agencies in preventive medicine or in any legitimate function of government in relationship to the care of the sick. By and with the aid of local, county, state and national medical organizations, the United States Public Health Service has been enabled to carry out far reaching plans for the control of venereal disease, of pneumonia and of cancer, for the expansion of personal and public hygiene and for the prevention of infections. Without such participation these accomplishments would never have been attained.

MEDICINE NOT IN POLITICS

The American Medical Association and its constituent bodies have constantly opposed any attempts on the part of local, county, state or federal governments to make medical care a political issue. American medicine fears political bureaucracies. It fears the acceptance of European models which have been set up by various so-called philanthropic foundations in an attempt to socialize medical practice in this country. The medical profession of this country wishes to keep the practice of medicine within the medical profession. It does not conceive that any political agency can do the job with one-tenth the efficiency at ten times the cost.

THE PRINCIPLE OF INSURANCE

The American Medical Association has never opposed the principle of insurance. An organization such as ours is in itself of the nature of a cooperative group in which individuals have banded together and by their individual contributions have made possible great accomplishments which individually they could not have attained. It is not the principle of insurance that is opposed by American medicine. The principle which we do oppose is political administration and manipulation of the insurance organization, devotion of a considerable portion of the funds thus derived to the payment of great numbers of employees not directly concerned with the service but intimately concerned with the maintenance of a political organization, and expansion of such organizations to wield greater and greater power in the affairs of the nation.

The American Medical Association has not opposed insurance against the costs of sickness, of disability, of unemployment, of old age or of death. It does oppose any interference by any outside agency—commercial, governmental or otherwise—into the relationship between doctor and patient which is fundamental in good medical care.

PERSONAL RELATIONSHIP BETWEEN DOCTOR AND PATIENT

We have recently heard the statement that the worth of this relationship is a fancied one; yet it possesses reciprocal qualities that inure to its value both to the physician and to the patient. With the realization by the physician that the patient in selecting him for personal service has demonstrated a confidence in his ability and integrity comes a determination to justify such trust by giving service to the best of his ability. The family physician knows the ancestry and heredity of the patient, is familiar with his temperament, the conditions under which he lives and his financial and emotional worries, and has a sympathetic attitude toward his problems—collective knowledge that has a definite value in carrying one through the crises of illness and in thwarting or minimizing the encroachment of disease.

In the National Health Conference a number of speakers who participated drew a picture of the American people in which perspective was largely lost. They showed us not only as a nation in which one third of the people are ill fed,

ill housed and ill cared for in sickness, but a nation with numbers of people suffering agonies because unable to purchase medical care, unwilling to consult a physician for fear of the costs of such consultation, and dying because of lack of medical care. The presentation of this perspective without suitable correction was unfair not only to the medical profession but also to the people of this country.

There is need for far more factual knowledge than is thus far available. An attempt to secure such factual knowledge is being undertaken by the American Medical Association as a part of its nationwide survey of medical care. The reports of some of the counties already published in THE JOURNAL indicate that it is possible to make this survey an accurate picture of the status of medicine in every portion of the country. Without such a picture it is impossible for any agency to develop suitable scientific legislation to meet the actual needs that exist.

It is proposed that at the next convening of the Congress of the United States legislation will be introduced to put into effect the proposals involved in the national health program. It is a function of this House of Delegates to consider carefully the proposals that are made so that your representatives, your elected and employed officers, may carry into effect your point of view and bring that point of view suitably to the elected representatives of the people.

HOUSE OF DELEGATES SPEAKS FOR PROFESSION

Only this body speaks for the American medical profession as a whole. It is no secret that there has been an attempt in various places to lead the American people to believe that the American Medical Association is not representative of the American medical profession, that it is a weakened, disrupted and failing organization. The actual fact is that the Association speaks today with the greatest membership in its history. During the year 1937-1938 it gained more than 4,000 members, reaching a total of 110,000 in its membership.

When your decision is made during this special session of the House of Delegates, it will be broadcast by the press and by your own organs of expression to the people and the medical profession in this country. The principles and policies which we have thus far established do not forbid, nor have they ever contemplated, any opposition to a well considered, expanded program of medical service when the need can be established. Neither is there any fundamental principle or policy which in any manner opposes aid to the indigent or the medically indigent if their indigence can be established. The principles and policies which this House of Delegates has adopted in the past have been developed with the single purpose of maintaining the quality and standards of medical care. To these high ideals I would urge you again to adhere. I would urge you also to consider seriously the obligation which rests on you, so that you may speak, when you do speak, with a united voice, and so that by and with your leadership the physicians of this country may also speak with a united voice in behalf of greater medical service and a greater medical profession.

Address of President-Elect Rock Sleyster

The Speaker presented the President-Elect, Dr. Rock Sleyster, Wauwatosa, Wis., who delivered the following address, which was referred to the Reference Committee on Reports of Officers and Board of Trustees:

For some years various groups have gradually been promulgating in our country an entirely artificial sentiment for the introduction into this country of foreign systems of medical care. This propaganda has been well financed, skillfully directed by professional promoters and carefully disguised in the name of "humanitarianism."

When our country followed others in a state of worldwide depression, a period of greatest prosperity ever known was followed by unemployment. A large part of our people who had failed to save for a rainy day found themselves in actual want. Others were forced to curtail and economize. Standards of living never before enjoyed by any people were lowered. Necessities became more difficult to attain, and many luxuries formerly enjoyed were impossible. Conditions have not improved. All of this has contributed to a state of mind

ready to seize any scheme promising greater social security. A people formerly independent have through want become susceptible to promises of a panacea, with little inclination to consider deliberately the price they will be forced to pay.

The proponents of these plans either fail to understand or deliberately fail to present the problem of medical care as merely a part of the picture as a whole. While we hear much of the "ill fed, the ill housed and the ill clothed," little, if anything, is said of these conditions as they relate to the creation of a medical problem. Physical needs as a contributing cause of illness get scant attention in the spotlight focused only on medical needs. The cart is put before the horse; the blame for unemployment is placed on illness instead of the blame for illness being placed on needs created by unemployment, in spite of the fact that millions in the ranks of the unemployed are physically well and unable to find work. Cause and effect are ignored and we are asked to concentrate on effects and to ignore causes.

The results of haphazard surveys of small sections of the population conducted by inexperienced relief workers are quoted as fact and are placed in the hands of admitted proponents of these schemes for interpretation and analysis. The results are presented as a new discovery. It is not stated that the medical problem is coexistent with the need of food, clothing, shelter, heat and light, and only a part of a whole. No credit is given to a profession which has given a million dollars a day in free service and which has rendered millions more at a cost far below its expense of delivery. What comparable record have the purveyors of other necessities of life to offer?

Whatever criticism may be aimed at the American Medical Association, the fact remains that the medical profession itself, voluntarily and from a sense of duty, is responsible for about everything "social" in the practice of the healing arts today. It would seem hardly necessary to enumerate to this group the social benefits to the people of this country which can be credited only to the medical profession. In the last half century no science has advanced as rapidly as medicine, and no benefits have been brought so promptly and unselfishly to the uses of the public as those given by the medical profession. We have been so engrossed in our work, however, that we have presumed that public opinion correctly evaluated these benefits and gave credit where credit was due.

Now cleverly prepared and financed propaganda is released to depict medicine as backward, selfish, conservative and indifferent to the public need. Now we are told that we have not done enough!

I am proud of the record we have made; I am proud of the men who make up this organization. They are the men who are caring for the great masses of our people. I am proud of men who are traveling lonely country roads at night, who are bringing babies into the world at daybreak, who are taking the responsibility of human life in their hands in the operating room, who are saving sick children, who are easing the pain of the aged and who are friend, counselor and father to their people. These are the men who make up the American Medical Association.

The meetings of this Association, faithfully attended, are given over primarily to a serious study for improving service to the sick. Hours and wages have never been subjects for discussion. Our resources are spent on educational endeavors so that our members may better serve. Our publications are devoted to the science of medicine so that all that is new may be brought to the bedside of the sick, even in the most remote districts. I challenge any one to find in the pages of our publications anything that reflects in any way a selfish interest. Our discoveries are given freely, promptly and without individual profit to humanity. Our services are given within the means of the receiver to pay. Our charities are unequalled in the history of the world. Our advance in self improvement and in scientific discovery has never been rivaled. The expectancy of life has been doubled, and plagues have been conquered. The world has been made a safer, better and happier place in which to live a life that has been lengthened through our efforts. Fraud and quackery have been exposed, and legislation protective to the people has been enacted. Education has been advanced, and hospital standards have been elevated. The people have been taught how to avoid illness. Research has

been encouraged and financed. The highest standards of ethics of any profession or trade that the world has ever known have been required of our members. Never at any time, in any way or in any place have our activities been motivated by a single selfish purpose. This is the organization of which I am proud; yet this is the organization which is accused of being backward, conservative, selfish and indifferent to human need.

Since the last meeting of this body, a National Health Conference, called by the Federal Interdepartmental Committee to Coordinate Health and Welfare Activities, was held at Washington on July 18-20. The proceedings of this meeting have been reported to you through *THE JOURNAL*. At this meeting a national health program was announced and definite proposals were made. You have been called in special session to consider them and to formulate the policies of this Association as it relates to them. Your officers and Board of Trustees will be charged with the responsibility of upholding these policies until you meet again. Representing the 110,000 members of this Association, your voice is the voice of American medicine. I have every confidence in the wisdom of such action as you will take.

In the consideration of these proposals we are motivated by but one thought. If enacted, what will each proposal contribute to the prevention of disease, to the prolongation of life and to the alleviation of suffering? At what cost will these things be accomplished; in other words, "What price glory"? To what will this effort lead? Are temporary advantages to be lost and offset by later disadvantages? These are questions that must be studied and weighed most carefully. To plans which will benefit the people we serve, we offer our wholehearted and unselfish support. That is our plain duty. It is equally our duty to oppose in every way at our command unsound doctrines which would eventually lower the standards of medical service to that found in other countries where the physician has been made subservient to political control.

American medicine has never stood still. We are deeply conscious of improvements to be made in the distribution of medical care. We have believed that no one plan can fit the needs of every section and that each community must be treated according to its needs and its local conditions. We have believed that no plan can be successful without the wholehearted cooperation of the medical profession and that government, if sincere, will recognize that fact. We have recognized one, and only one, great responsibility: that to the people of our country. We have offered our hearty cooperation in perfecting our service to them. We will not be a party to any plan which lowers the quality of service even to the poorest family. Maintaining our constant advance in the science of medicine, we are dedicated to a distribution of the highest possible type of service to the people at a cost they can afford to pay. The care of the sick must not be given over to commercial groups in open competitive bidding, each offering a little more for a little less. It must not be dominated by political control. In the development of any plan, it is our plain duty to the American people to see that the structure of medicine is not wrecked, for their future health and happiness depends on its constructive advance. It must not be destroyed.

In peace or in war, the medical profession has never failed the people of our country. It will not fail them now. Their needs are our needs, and they will be met as they have always been met by those who, through daily contact and care of the sick, know these needs better than any one else. Our record is an open book and we invite full comparison of unselfish and efficient public service with any other agency.

Statement of the Board of Trustees

Dr. Arthur W. Booth, Chairman, presented the following statement, which was referred to the Reference Committee on Reports of Officers and Board of Trustees:

For the third time in the history of the American Medical Association your Board of Trustees, in accordance with the power conferred on it by the By-Laws of the Association, has called you into a special session. On two previous occasions—once when our country was at war and the services of the American Medical Association were required to provide medical officers for our troops and physicians to aid in the work

of the selective service boards, and a second time when the Social Security Act was first proposed to the Congress—you were called into special session. The specific purposes for which you have been called on this occasion have been announced to you by the Speaker of the House of Delegates and by the Secretary of the Association.

Following the presentation of the statement of Miss Josephine Roche to the House of Delegates at the San Francisco session, the National Health Conference met in Washington, July 18, 19 and 20. From that conference there emanated, as you already know, a National Health Program developed by a technical committee, which, in turn, had been appointed by the Interdepartmental Committee to Coordinate Health and Welfare Activities appointed by the President of the United States. The National Health Conference was a meeting attended by representatives of labor and welfare agencies, medical organizations, social workers and other groups. The program which is now presented to you was presented to the National Health Conference by representatives of various governmental agencies responsible for the conference and by the Technical Committee that has been mentioned. Little opportunity was given for discussion by those in attendance on the Conference of the specific proposals that were made. The President of the Association, your Secretary, the Chairman of the Board of Trustees, the Editor of *THE JOURNAL*, the Chairman of your Committee on Medical Care, and the chairmen of your council on Scientific Assembly and that on Industrial Health, who were invited individually to participate in the Conference, all made clear to the Conference the fact that only the House of Delegates of the American Medical Association is empowered to establish policies and that only the House of Delegates may establish for the American Medical Association a policy relative to the various proposals that were made. In submitting these proposals to you the Board would point out that at the calling of the National Health Conference it was stipulated that no formal action would be taken by that Conference. Nevertheless, responsible representatives of the government have indicated that the proposals made would be embodied in legislation to be submitted to the Congress of the United States when next it meets.

For these reasons and particularly because the Congress of the United States will be convened before the House of Delegates will again meet in regular session, the Board of Trustees considered it advisable to request the Speaker to call this special session of the House of Delegates in order that your representatives may be able to present your point of view, as representative of the American medical profession, to the people and to the Congress of the United States and to take such other action as may be deemed necessary to make your views effective.

The Board of Trustees will not at this time read to the House of Delegates in detail the complete text of the proposals or even the abstract of the five chief proposals that have been made. These proposals concern briefly (1) expansion of public health service, (2) increase of hospital facilities, (3) medical care for the medically indigent, (4) a general program for medical care and (5) a program for compulsory sickness insurance covering the entire population of the United States.

These five proposals, it has been suggested, may well be submitted to five special reference committees of this House of Delegates, each of which will concern itself with the details of one of these five proposals and at the same time give consideration to such alternative proposals for meeting the same needs as may arise from the medical profession itself.

The complete text of the proposed National Health Program was published in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* immediately after the conclusions of the National Health Conference and has thus been made available to the entire medical profession of the country. In order, however, that you may have this material immediately before you, there is now being given to each of you a copy of the complete text of the National Health Program to be used in your consideration of this subject.

In submitting these proposals to the National Health Conference the statement was made by various representatives of our government that it was not contemplated that this entire program would be made immediately effective but rather that there might over a term of approximately ten years be developed

such a program, according to the "blue prints" offered, so that expansion of medical and public health activities in the United States during the next ten years might follow the definite procedure here outlined. On you, therefore, rests a serious burden—the burden not only of planning for the immediate needs in the field of medical care in the United States but also of setting forth the policies and views of the medical profession in relationship to medical care and in relationship to this "blue print."

Your responsibility is great. The medical profession of the entire country awaits anxiously the answer that you will make. Recognizing the manner in which the House of Delegates has in the past accepted the obligation placed on it to represent the point of view of 110,000 American physicians, of whom you are the authorized representatives, we are confident that you will make your decisions calmly, carefully, and with the same sympathetic consideration for the needs of the people of this country that has characterized your actions in the past.

The results of your deliberations as expressed in this special session of the House of Delegates will be the guiding and determining voice for the medical profession on those whom you authorize to make your voice effective, until the House of Delegates may at some future time determine any other action.

INVESTIGATION BY THE DEPARTMENT OF JUSTICE

Shortly after the termination of the National Health Conference, an announcement was released to the newspapers and to the press of the United States indicating that the Department of Justice of the United States government proposed to seek an indictment of the American Medical Association as a monopoly, unless the American Medical Association, through its central organization or through its constituent society in the District of Columbia, consented to certain stipulations satisfactory to the Department of Justice in relationship to the nature of medical practice. An investigator from the Department of Justice has consulted some of the correspondence in the headquarters office of the American Medical Association. At no time has an official or unofficial communication ever been received from the Attorney General of the United States, Homer Cummings, or from his assistant, Thurman Arnold, or from any other representative of the Department of Justice. The Association knows of this matter otherwise only through the statements released to the press.

In response to numerous inquiries that have come to the officers of the Association and to the headquarters, the statement has been made repeatedly that the American Medical Association welcomes investigation by any authorized agency of the nature of its organization, of its methods of work, of the conduct of its affairs and of its activities, firmly reliant on the belief that every action taken by the Association has been in accordance with its constitutional organization in the interest of the public welfare, and for advancing the standards and quality of medical service for the American people; and that at no time has it violated the established law of the federal, state or municipal governments of this country. Moreover, by the very nature of its organization, it has observed constantly the democratic principles on which the government of the United States is founded and maintained.

SOCIAL SECURITY ACT

As this House of Delegates is aware, the American Medical Association is a federacy of its constituent associations, established to promote the science and art of medicine and the betterment of public health. In accordance with the provision of the Social Security Act, an organization of this type is considered to be exempt from those stipulations of the act assessing taxation. According to the original ruling of a deputy commissioner of internal revenue, the American Medical Association has been until recently exempt from these provisions. It has indeed proposed to establish voluntarily a plan for the security of the employees of the Association, and this plan was approved by the House of Delegates at the San Francisco session. More recently special interpretation of the law has been made by another deputy commissioner whereby the American Medical Association, formerly classified with

educational and scientific groups, is now classified as a business league and required under the act to pay considerable tax covering all its employees. Your Board of Trustees, after careful consideration, has determined to appeal from this interpretation and accordingly has employed special counsel to undertake the handling of this appeal to restore the Association to its original and proper classification as a scientific and educational organization. The appeal made by your Board of Trustees is not an attempt to evade the requirements of any legislation enacted by the Congress of the United States. We have in the past conformed fully to every law, and it is our purpose that we shall continue to conform to the law if, as and when it may be established by the courts of the United States that the interpretation of the law by various governmental agencies is in accord with the opinion of the courts that this is the law.

In view of the exigencies of the present situation the Board of Trustees deems this not a suitable time to discuss at length the subject of public relations. It wishes to assure you that the subject has been given serious consideration and that steps have been taken to expand activities relating to this matter.

Representatives of American Dental Association

The Secretary announced the presence of four representatives of the American Dental Association, who, on request, arose and were recognized by the House.

Reference Committees

On motion of Dr. E. L. Henderson, Kentucky, seconded by Drs. H. B. Everett, Tennessee, and James E. Paullin, Section on Practice of Medicine, and carried, the suggestion of the Speaker was adopted, namely, that there be three general reference committees: one to consider reports of officers and Board of Trustees; a second to consider the main subject stated in the call, this committee to be composed of the chairmen of five subcommittees, and a third committee on miscellaneous business.

The Speaker presented the following names of members of reference committees:

CONSIDERATION OF THE NATIONAL HEALTH PROGRAM

Walter F. Donaldson, Chairman, Pennsylvania.
Fred W. Rankin, Section on Surgery, General and Abdominal.
H. A. Luce, Michigan.
Walter E. Vest, West Virginia.
Frederic E. Sondern, New York.

DIVISION 1 TO CONSIDER RECOMMENDATION NO. 1 ON EXPANSION OF PUBLIC HEALTH SERVICES

Walter E. Vest, Chairman, West Virginia.
A. A. Walker, Alabama.
Ben R. McClellan, Ohio.
James O. Graves, Louisiana.
James R. McVay, Missouri.

DIVISION 2 TO CONSIDER RECOMMENDATION NO. 2 ON EXPANSION OF HOSPITAL FACILITIES

H. A. Luce, Chairman, Michigan.
Holman Taylor, Texas.
George Blumer, Connecticut.
Francis F. Borzell, Pennsylvania.
J. C. Flippin, Virginia.

DIVISION 3 TO CONSIDER RECOMMENDATION NO. 3 ON MEDICAL CARE FOR THE MEDICALLY NEEDY

Walter F. Donaldson, Chairman, Pennsylvania.
E. H. Skinner, Section on Radiology.
F. S. Crockett, Indiana.
Fred Moore, Iowa.
J. E. Paullin, Section on Practice of Medicine.

DIVISION 4 TO CONSIDER RECOMMENDATION NO. 4 ON A GENERAL PROGRAM OF MEDICAL CARE

Fred W. Rankin, Section on Surgery, General and Abdominal.
Richard H. Miller, Massachusetts.
Grant C. Madill, New York.
John H. Fitzgibbon, Oregon.
H. L. Snyder, Kansas.

DIVISION 5 TO CONSIDER RECOMMENDATION NO. 5 ON INSURANCE AGAINST LOSS OF WAGES DURING SICKNESS

Frederic E. Sondern, Chairman, New York.
Charles J. Whalen, Illinois.
Edward M. Pallette, California.
Andrew F. McBride, New Jersey.
Henry C. Macatee, District of Columbia.

REPORTS OF OFFICERS AND BOARD OF TRUSTEES

Terry M. Townsend, Chairman, New York.
William F. Bransch, Minnesota.
E. L. Henderson, Kentucky.
Samuel P. Mengel, Pennsylvania.
C. W. Roberts, Georgia.

MISCELLANEOUS BUSINESS

W. H. Seemann, Chairman, Louisiana.
Charles B. Reed, Illinois.
McLain Rogers, Oklahoma.
H. G. Hamer, Indiana.
Felix J. Underwood, Mississippi.

SERGEANTS AT ARMS

J. D. Brook, Michigan.
Griffith E. Thomas, U. S. Navy.

Resolutions Recommending Conference to Formulate Working Agreement for Compensation for Medical Care

Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, presented the following resolutions, which were referred to Division 3 of the Reference Committee on Consideration of the National Health Program:

WHEREAS, At present doctors are engaged in a desperate struggle to resist the encroachments of socialized medicine and the enemy has already undermined the foundations of individualistic medicine; and

WHEREAS, More than 50 per cent of what was formerly paid practice has been absorbed by public free agencies, so that all we may hope to accomplish is to salvage the remaining 50 per cent to keep our self respect; and

WHEREAS, The physician has lived through many years of voluntary servitude with increasing financial demands and decreasing compensation, with growing competition from public medical and social agencies for which the doctor works with poor pay or none at all, such as free teaching, free clinics, free hospitals, industrial and insurance medical organizations, and ever growing activities of boards of health. These are unsatisfied with the police function in the control of contagious and infectious disease and the administration of health laws but now include pregnancy and diseases of the eye, ear, nose and throat in bureaucratic fashion taking over the actual practice of medicine; and

WHEREAS, We have listened to the siren voices of the Lorelei crew of welfare and social workers who have taken advantage of the altruistic and sentimental attitude we have developed through centuries of constant love for and contact with sick humanity. The elimination of disease on every forward march has been taken by and under the leadership of doctors, and it must remain so. The great army of doctors and specialists, with the doctor first and the specialist second, must be maintained in any plan adopted; and

WHEREAS, The cost of medical care has become a burden to the people and the profession and operating, x-ray and laboratory equipment has become essential to progressive medicine and surgery; be it

Resolved, That a conference be held between the Board of Trustees of the American Medical Association, the members of the Council on Medical Education and Hospitals, the executive committee of the American Hospital Association, the executive committee of the Advisory Board of Medical Specialties and the executive committee of the American College of Surgeons, together with the proper medical authorities of the U. S. government, to formulate a working agreement whereby the U. S. government will compensate the qualified medical profession and those on the staffs of all approved hospitals, dispensaries and laboratories for the medical care of those unable to pay for necessary service for proper diagnosis and treatment; and be it further

Resolved, That the approved hospitals, dispensaries and laboratories be given such subsidy and necessary financial aid as may be required to meet the actual cost of medical care, that these indigent patients be returned to the family physician after hospital care, and that the doctor receive such compensation for office and bedside service as may be agreed on by the county medical society through the Board of Trustees of the American Medical Association and the medical authorities set up with the U. S. government; and be it further and finally

Resolved, That nothing in this resolution may be construed to imply that the receipt of any compensation from any source involves anything other than that the control and direction of expenditures shall be within organized medicine and under the advice and consent of the American Medical Association without dictatorship or bureaucracy.

A motion of Dr. Carl F. Vohs, Missouri, that the plans and proposals to be presented to the House be referred to committees by title and not read to the House was lost.

Resolutions on Distribution of Medical Care

Dr. Hilton S. Read, New Jersey, presented the following resolutions, which were referred to Division 3 of the Reference Committee on Consideration of the National Health Program:

WHEREAS, The art and science of medical care in the United States is held in universal esteem; and

WHEREAS, The distribution of said medical care and the cost thereof in the United States is under surveillance; and

WHEREAS, There are reasons to believe that said distribution may be in need of modification; therefore be it

Resolved, That this Association states as its belief that the care of the medically indigent is the dual responsibility of the physicians and government, who should jointly cut the pattern of such medical care; be it further

Resolved, That this Association approves the experimental approach in the provision of medical care being undertaken by component societies of

this Association as the proper approach to the solution of a geographically and economically complex problem; and be it further

Resolved, That this Association commends the continued considerate cooperation of all interested parties to a joint effort to solve this problem.

Resolution Recommending Proposals for Financing Care of Indigent Sick

Dr. E. G. Wood, Tennessee, presented the following resolution, which was referred to Divisions 3 and 4, and any other divisions deeming it appropriate for their consideration, of the Reference Committee on Consideration of the National Health Program:

WHEREAS, The national health program as submitted to the National Health Conference by the Interdepartmental Committee and now before the House of Delegates of the American Medical Association for consideration contains provisions which do violence to the ethical principles that we regard as essential to good medical care; and

WHEREAS, A better understanding of our position on the questions involved in this issue may be conveyed to all concerned by making a positive proposal in which are embodied the principles we regard as essential to good medical care to indigent and nonindigent persons alike; therefore be it

Resolved, That the House of Delegates of the American Medical Association adopt the following proposals to the end that the American people may have a clear understanding of our position.

PROPOSALS

It is proposed that the Congress of the United States enact a statute in accord with the following principles:

I. MEDICAL INDIGENCE DEFINED AND CLASSIFIED

Indigence shall be defined, and those persons who are indigent within the definition of this act shall be classified as (a) completely indigent or (b) relatively indigent, in accordance with the following definition of the terms *indigent* and *relatively indigent*.

The word "indigent" as used in this act is meant to refer to (1) a person who has no resources and no income and (2) a person who has an income, in money or nonmoney or both, but whose income of all types and from all sources when judiciously expended for the necessities of life, such as food, clothing and shelter, leaves no residue with which to pay for medical care.

The term "relatively indigent" refers to persons with an income, in money or nonmoney or both, which when judiciously expended for the necessities of life leaves a residue which may be applied to the cost of medical care but which is too small in amount to cover the reasonable cost of hospital care, when needed, or the costs of medical care at home in case of a serious or prolonged illness.

The eligibility of a person or family to the benefits provided for the relatively indigent can be determined by the proper agency when the injury or illness arises.

II. CERTIFICATION AND REGISTRATION OF INDIGENTS

Each citizen who is at any time found to be indigent, or on application therefor or otherwise, shall be given a certificate identifying him and those dependent on him, under proper regulations to be determined by the administrative agency created by the act and reciting whether the holder is completely indigent or relatively indigent.

Such certification shall show the date of its issuance and expiration, and the administrative agency established by the act shall have the power, and be charged with the responsibility of, adopting and enforcing reasonable regulations for the prevention of fraudulent procurement or use thereof, including cancellation of any such certificate held by a person who is not in fact indigent or whose indigence is removed after issuance. Temporary certificates may be issued, renewable on evidence of continued indigence.

III. THE PAYMENT OF THE COST

Provision shall be made for the payment by the administrative agency of the cost of necessary medical care rendered to the holder of a certificate of indigence, or to his dependents listed and identified thereon, by any practitioner licensed to attend and prescribe for sick persons by the state in which the service is rendered, or by any hospital (including clinics and laboratories) approved by such attendant practitioner, under the following conditions and limitations:

1. The medical care to be so provided for the holder of a certificate of complete indigence and his dependents listed thereon shall include whatever may be necessary to effect restoration to health, such as treatment by his attendant practitioner in home or office, hospital care or laboratory service, with the end in view that all available resources and facilities for medical care may be made responsive to the needs of such persons.

2. The medical care to be so provided for the holder of a certificate of relative indigence and his dependents shall be limited to cases of illness or disability which are so prolonged or of such character as to require institutional care or some form of special or unusual treatment the expense of which is in excess of the financial ability of the certificate holder except by depriving him or his dependents of necessary food, clothing or housing.

CERTIFICATE COMPLETE AUTHORITY FOR COMPLETE CARE

3. The practitioner or hospital called on by the holder of a certificate of complete indigence for medical care for himself or dependents shall render all necessary and reasonable care which the condition of the patient requires without further authority from the agency, and the agency shall be liable for the reasonable cost thereof.

LIMITED CARE ON CONDITIONS

4. The practitioner or hospital called on by the holder of a certificate of relative indigence for medical care for himself or dependents shall promptly report the needs of the patient to the agency under rules to be prescribed, and the agency shall be liable for the cost thereof only when expressly authorized, provided that in emergency cases failure to obtain prior authority shall not avoid such liability in proper cases subsequently approved.

INSTITUTIONS FOR MENTAL DISORDERS NOT AFFECTED

5. Persons requiring permanent or prolonged confinement because of mental disorders shall continue to be the responsibility of local governmental subdivisions as now.

POWERS VESTED IN ADMINISTRATIVE AGENCY TO MAKE REGULATIONS

6. The administrative agency created by the act shall be authorized to adopt regulations requiring prompt reports of medical care rendered to any certificate holder for which compensation by the agency is expected, including report of diagnosis, number of calls made and anticipated, reasons for hospitalization, and any other pertinent facts which will enable the agency to determine the reasonableness of or the necessity for the care furnished, and such reports may be required during the progress of treatment. Such reports, which the agency shall cause to be communicated to the proper public health authorities, shall give special consideration to conditions rendering preventive precautions desirable in order to avoid recurrence or repetition of such illness or disability.

POWERS TO FIX SCHEDULE OF FEES

7. The administrative agency created by the act shall, after investigation, establish a schedule of fees which may be charged by practitioners or institutions for medical care furnished to certificate holders or their dependents. This schedule may from time to time be changed, altered or modified in the discretion of the agency. It may classify fees according to the population of communities in which medical care is rendered or according to any other reasonable differential, local conditions always being considered.

POWERS TO REFUSE PAYMENT ON CONDITIONS

8. The administrative agency shall pay all reasonable fees submitted by practitioners or hospitals for medical care rendered to certificate holders and their dependents within the schedule adopted by the agency, provided that no such fee shall be paid for services found by the agency to have been unnecessary or unreasonable or which may have been rendered after notice from the agency that no further medical care is needed or efficacious in a particular case or when required reports have been wilfully omitted.

The decision of the agency that fees submitted by a practitioner or hospital shall not be paid because of failure to comply with its regulations for reports or because of the agency's determination that the services for which the fees are rendered were unnecessary or unreasonable shall be final and conclusive and not subject to review except for arbitrariness, illegality or contumacy on the part of the agency's officers or agents.

9. The administrative agency shall be expressly authorized and directed:

(a) To investigate, through a competent medical authority, the adequacy of the medical care of certificate holders and their dependents; to consult on cases when called on by attendant practitioners or on initiative of its medical officers when they have reason to believe that inadequate care is being furnished, and to refer a patient to a diagnostic center for study when the diagnosis is obscure or there is difference of medical opinion thereon and when the patient consents to such reference.

(b) To investigate conditions of fraud on the part of practitioners, hospitals or certificate holders when there is reasonable cause therefor, as in the case in suspected malingering or unnecessary or excessive visits or treatments.

(c) To report to the proper state licensing or prosecuting authorities and to any local professional association any cases of unethical or illegal practices or conduct on the part of practitioners or hospitals in the care of certificate holders which in any way may be brought to the attention of the agency.

IV. PROVIDING APPOINTMENT OF NATIONAL BOARD

The act shall be administered by a National Board of Medical Care consisting of thirteen members appointed by the President. Two members of such board shall represent the opinion of social service workers, three members the opinion of the medical profession, one member the opinion of hospital administration and seven members the opinion of the taxpayer and patient.

Such Board shall, through as many state, sectional or district and local boards as may be necessary, proceed to determine, register and certify the indigent citizens who may be entitled to the benefits of the act and shall supervise and direct the activity of all such subordinate boards in such manner as it may provide. Such supervision and direction, under regulations adopted by the Board, may be delegated to a national director of medical care, appointed by the Board, who shall devote his full time to such duties.

PROVIDING FOR THE CREATION OF EXECUTIVE UNDER NATIONAL BOARD

The National Board shall hold meetings at stated intervals and shall be paid a per diem and expense. Extraordinary meetings will be held on the call of the Director. The schedule of fees and all policies of administration shall be determined and fixed by the National Board. This Board will also determine what state, sectional and local boards are necessary, appoint them, determine their duties and authorize the appointments of medical and administrative officers and employees.

Full time county health departments as constituted at present, when possible, should be designated the local administrative agency for the area over which the department has jurisdiction.

In localities where full time health departments do not exist, in a county or group of counties, steps should be taken to create such an administrative agency for the proper area.

Resolutions on Public Announcement of Plans Recommended by House of Delegates

Dr. George L. Laverty, Pennsylvania, presented the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The Social Security Act of Congress made possible the creation of an Interdepartmental Committee to Coordinate Health and Welfare Activities; and

WHEREAS, The Chairman of said Interdepartmental Committee convened a session known as the National Health Conference; and

WHEREAS, Various proposals there discussed are economically extravagant, sociologically impracticable, scientifically stifling and professionally deteriorating; and

WHEREAS, The President of these United States did publicly proclaim that a "coordinated national program of action" is imperative; be it

Resolved, That the Dauphin County Medical Society, through the duly constituted Medical Society of the State of Pennsylvania, does hereby petition the American Medical Association

(a) To announce, publish, proclaim and promulgate by commercial radio, press release, paid advertisement and public acclaim such specific methods and measures as its duly constituted officers and its House of Delegates recommend as practicable and expedient, within scientific and economic limits, in the prevention of illness, and the conservation of the health of the citizens of the nation, and

(b) To combat, oppose, contradict and amend, by the same means, such idealistic, fanciful, impracticable and extravagant schemes as will rebound eventually to encourage malingering, stifle initiative, retard progress and disrupt the traditional physician-patient relationship; and be it further

Resolved, That the proper representatives of the American Medical Association be empowered also to accept voluntary contributions from individuals and organizations, lay and professional, who may choose to assist in underwriting the expense incident to this proposed effort.

Report of Reference Committee on Credentials

Dr. Deering G. Smith, Chairman, reported that 153 delegates had registered, and recommended that Drs. James C. Sargent and Stephen E. Gavin be seated as delegates from Wisconsin.

The report of the reference committee was adopted on motion of Dr. Smith, seconded by Dr. E. G. Wood, Tennessee, and carried.

Proposed Substitute for Title VI of the Social Security Act

Dr. Arthur T. McCormack, Kentucky, presented the following proposed substitute for Title VI of the Social Security Act, which was referred to the divisions of the Reference Committee on Consideration of the National Health Program deeming it appropriate for their consideration:

TITLE VI

PUBLIC HEALTH WORK

SECTION 601-A. For the purpose of assisting states, counties, health districts and other political subdivisions of states in establishing and maintaining adequate public health services, including the training of personnel for local and public health work, there is authorized to be appropriated for the fiscal year ending June 30, 1940, the sum of \$15,000,000.00; and for the fiscal year ending June 30, 1941, the sum of \$20,000,000.00; and for the fiscal year ending June 30, 1942, the sum of \$30,000,000.00; and for the fiscal year ending June 30, 1943, the sum of \$40,000,000.00; and for the fiscal year ending June 30, 1944, the sum of \$50,000,000.00; and thereafter for each fiscal year such amounts as may be found necessary, not exceeding in any fiscal year \$100,000,000.00, to be used as hereinafter provided.

B. For the purpose of assisting States, counties, legally established districts and other political subdivisions of States, in establishing and maintaining medical care for the medically needy, including the training of personnel for such purposes, there is authorized to be appropriated for the fiscal year ending June 30, 1939, the sum of \$50,000,000.00; for the fiscal year ending June 30, 1940, the sum of \$75,000,000.00; for the fiscal year ending June 30, 1941, the sum of \$100,000,000.00; and for each fiscal year thereafter such sums as may be found necessary but not exceeding in any fiscal year \$200,000,000.00, to be used as hereinafter provided.

C. For the purpose of assisting States, counties, health districts and other political subdivisions of the States in the construction of additional hospital facilities, including health centers, for the medically needy, especially in rural areas, there is hereby authorized to be appropriated for the fiscal year ending June 30, 1939, the sum of \$25,000,000.00; for the fiscal year ending June 30, 1940, the sum of \$25,000,000.00, and for each of the ten years thereafter, the sum of \$50,000,000.00.

STATE AND LOCAL PUBLIC HEALTH SERVICES

Section 602-A. a. The Surgeon General of the Public Health Service, with the approval of the Secretary of the Treasury, shall, at the beginning of each fiscal year, allot to the States the total of (1) the amount appropriated for such year pursuant to section 601-a; and (2) the amounts of the allotments under this section for the preceding fiscal year remaining unpaid to the States at the end of such fiscal year. The amounts of such allotments shall be determined on the basis of (1) the population; (2) the

special health problems, including the strengthening of public health organization, the eradication of tuberculosis, venereal diseases and malaria, the control of mortality from pneumonia and cancer, mental hygiene and industrial hygiene; and (3) the financial needs of the respective States. On making such allotments the Surgeon General of the Public Health Service shall certify the amounts thereof to the Secretary of the Treasury.

b. The amount of an allotment to any State under subsection a for any fiscal year, remaining unpaid at the end of such fiscal year, shall be available for allotment to States under subsection a for the succeeding fiscal year, in addition to the amount appropriated for such year.

c. Prior to the beginning of each quarter of the fiscal year, the Surgeon General of the Public Health Service shall, with the approval of the Secretary of the Treasury, determine in accordance with rules and regulations previously prescribed by such Surgeon General after consultation with a conference of the State and Territorial health authorities, the amount to be paid to each State for such quarter from the allotment to such State, and shall certify the amount so determined to the Secretary of the Treasury. On receipt of such certification, the Secretary of the Treasury shall, through the Division of Disbursement of the Treasury Department and prior to audit or settlement by the General Accounting Office, pay in accordance with such certification.

d. The moneys so paid to any State shall be expended solely in carrying out the purposes specified in section 601-a, and in accordance with plans presented by the health authority of such State and approved by the Surgeon General of the Public Health Service.

B. a. The Surgeon General of the Public Health Service, with the approval of the Secretary of the Treasury, shall, at the beginning of each fiscal year, allot to the States the total of (1) the amount appropriated for each year pursuant to section 601-b; and (2) the amounts of the allotments under this section for the preceding fiscal year remaining unpaid to the States at the end of such fiscal year. No allotment shall be paid to any State under this section until it has provided in its State health authority, a bureau or agency for the medical care of the medically needy and that the director of such bureau or agency shall have been a legally qualified physician under the laws of such State for at least five years and shall have such other qualifications as may be provided in the regulations authorized hereunder; and (2) the amounts of the allotments under this section for the preceding fiscal year remaining unpaid to the States at the end of such fiscal year. The amounts of such allotments shall be determined on the basis of (1) the population; (2) the special problems of medical need; and (3) the financial needs of the respective States. On making such allotments the Surgeon General of the Public Health Service shall certify the amounts thereof to the Secretary of the Treasury.

b. The amount of an allotment to any State under section a for any fiscal year, remaining unpaid at the end of such fiscal year, shall be available for allotment to States under subsection a for the succeeding fiscal year, in addition to the amount appropriated for such year.

c. Prior to the beginning of each quarter of the fiscal year, the Surgeon General of the Public Health Service shall, with the approval of the Secretary of the Treasury, determine in accordance with rules and regulations previously prescribed by such Surgeon General after consultation with a conference of the State and Territorial health authorities together with the directors of the bureaus of medical service, hereinbefore provided, the amount to be paid to each State for such quarter from the allotment to such State and shall certify the amount so determined to the Secretary of the Treasury.

d. The moneys so paid to any State shall be expended solely in carrying out the purposes specified in section 601-B and in accordance with plans presented by the health authority and director of medical service of such State, after consultation with representatives selected by the medical profession and approved by the Surgeon General of the Public Health Service.

C. a. The Surgeon General of the Public Health Service, with the approval of the Secretary of the Treasury, shall, at the beginning of each fiscal year for ten years, allot to the States the total of (1) the amount appropriated for such year pursuant to section 601-C and (2) the amounts of the allotments under this section for the preceding fiscal year remaining unpaid to the States at the end of such fiscal year. The amounts of such allotments shall be determined on the basis of the need of the States, counties, health districts and other political subdivisions of the States for general special hospitals for the care of cases suffering from tuberculosis or mental diseases or for diagnostic centers; (2) the financial needs; of the respective States. On making such allotments the Surgeon General of the Public Health Service, shall certify the amounts thereof to the Secretary of the Treasury.

b. The amount of an allotment to any State under subsection a for any fiscal year, remaining unpaid at the end of such fiscal year, shall be available for allotment to States under subsection a for the succeeding year, in addition to the amount appropriated for such year.

c. Prior to the beginning of each quarter of the fiscal year, the Surgeon General of the Public Health Service shall, with the approval of the Secretary of the Treasury, determine in accordance with rules and regulations previously prescribed by such Surgeon General after consultation with a conference of the State and Territorial health authorities and the directors of medical service hereinbefore provided, the amount to be paid to each State for such quarter from the allotment to such State, and shall certify the amount so determined to the Secretary of the Treasury. On receipt of such certification, the Secretary of the Treasury shall, through the Division of Disbursement of the Treasury Department and prior to audit or settlement by the General Accounting Office, pay in accordance with such certification.

The moneys so paid to any State shall be expended solely in carrying out the purposes so specified in section 601-C and in accordance with the plans presented jointly by the health authority of such State and the director of medical service of such State and approved by the Surgeon General of the Public Health Service; and, provided that before any allotment shall be made to any State under this section, the State and/or the county or other

legal subdivision shall have provided by law for the permanent and adequate maintenance for such hospitals or diagnostic centers.

The Secretary announced that the representatives of the National Medical Association were present, and the Speaker requested them to arise and be recognized.

Recommendations on Appointment of Special Executive Committee

Dr. E. N. Roberts, Idaho, presented the following recommendations, which were referred to the Reference Committee on Miscellaneous Business:

We respectfully acknowledge that no plan designed to meet the problems confronting our profession can reasonably be consummated except by the deliberation and conferences of men qualified by actual practice and special study for such work. We feel that the House of Delegates is too unwieldy a body for the successful development of such a plan, and that there is no other group within the American Medical Association sufficiently representative of the membership or qualified in other respects for work of such magnitude.

We acknowledge that the efforts made heretofore on the part of the leadership of the American Medical Association to meet this problem, which affects more than twenty million people and hundreds of millions of dollars, have not borne a reasonable relationship to the gravity of the problems involved.

We acknowledge that our profession has been placed inadvertently and unjustly in a position by which we are made to appear selfishly indifferent to the medical needs of the indigent.

We acknowledge that the quality of medical care received by the indigent will not be adversely affected by government aid in securing such care, and that our profession is prepared to welcome governmental financial aid in such a program, which must be administered by qualified physicians.

The House of Delegates of the Idaho State Medical Association recommends to our delegates to the special session of the American Medical Association:

1. That the House of Delegates form a special executive committee of men within the profession sufficiently large to include men of wide experience in medical economics.

That this committee remain in session continuously as long as may be required to formulate a policy for the care of the indigent.

2. That every effort be made by the American Medical Association to restrict participation in medical affairs on the part of the federal government to the portion of the population who are recipients of relief from the government.

3. That the medical profession recognize the real need for some further plan covering the medical needs of the low income class not on relief and examine sympathetically any plan put forward by the federal government based on the experience gained through the care of the indigent.

A Plan for Publicity Against Regimentation of Physicians

Dr. Walter E. Vest, West Virginia, introduced the following Plan for Publicity Against Regimentation of Physicians, submitted by the Parkersburg (W. Va.) Academy of Medicine, which was referred to the Reference Committee on Miscellaneous Business:

We represent a small group (sixty in number) of physicians in one of the smaller cities in a small state. Our academy of medicine has recently approved, and most members have lent support to, a plan for combating the evil of proposed "socialization of medicine." Our ideas regarding the situation are as follows:

1. It seems that certain socialistically minded individuals are determined to force the issue of "socialized medicine" through the next session of the Congress.

2. These groups likewise seem to consider that they can, by force and intimidation, prevent the medical profession from presenting its views in as far as formulating any workable plan is concerned.

3. The American Medical Association has, so far, not taken any decisive action in furnishing to the state or county medical societies any concrete plan of action.

4. A definite nation-wide plan of action is necessary at once so that the voting population can be reached and given medicine's side in the controversy.

5. Component medical societies are the best instruments whereby the facts can be presented in each specific locality.

6. Individual physicians composing these medical societies need not editorials in medical journals but personal instruction as to just what socialized medicine is and what to do about it.

With the above premises in mind, the Parkersburg Academy of Medicine, representing seven counties in West Virginia, has taken decisive action after consulting with officials of the state medical association. As far as we know, we are the first county medical society to approach the public openly on this subject. We feel that we have not been unethical or violated the accepted, ethical canons of the profession. We held several meetings, and one of us made a six weeks study of available literature. All angles of the problem were discussed, and finally most of the members of the Academy agreed on a publicity campaign. The salient points in this campaign are as follows:

1. Appointment of an information committee, which is responsible for all publicity.

2. Passage of a resolution embodying these principles:

- (a) A statement calling attention to the current agitation regarding "state controlled medicine," "governmental medicine," "socialized medicine" or other like terms.

- (b) Call attention to the fact that so far publicity regarding this issue has been of a biased nature.

- (c) Call attention to the fact that the medical profession has always been the first to attempt to protect public welfare.

- (d) State specifically that organized medicine is willing to cooperate in any and all ways, if given the opportunity, and to improve medical care for indigent and low-income groups.

- (e) The medical profession feels that it should be given the opportunity to plan, supervise and manage any "sickness insurance" plan.

- (f) Go on record as opposing regimentation of medical practice by politicians or other lay bodies.

These principles have been embodied in a resolution and were published in the local newspapers.

3. Contact with the local newspapers through the editors and reporters in an attempt to get these molders of public opinion on our side.

4. Assessment on the individual members of the medical academy for sufficient funds to carry on the campaign.

5. Attempt to give the newspapers stories of local interest, and to be careful that not too many articles are published since their news value will be impaired. It is suggested that two articles a week are sufficient. In some localities a system of serialized articles, running daily for a week, has been used.

6. We obtained literature from the Bureau of Medical Economics and distributed a package of eight pamphlets to every physician for his own education.

7. We obtained, with Dr. Leland's permission, a copy of his article entitled "Is Medicine to be Socialized?" and we had 10,000 copies printed. These pamphlets, with suitable placards, were placed in every physician's office where the general public quickly used them and took them to their friends. They were likewise placed in hospitals, drug stores and other public places.

8. We approached the various service clubs in the city and had prepared speeches delivered at their luncheon groups, feeling that this is the class of individual whom we must reach, namely the so-called middle class.

9. We have distributed, through fraternal orders and like organizations in their periodicals, short, easily understandable articles explaining socialized medicine.

10. We have written an open letter—and have had it published in our local newspapers—to all political candidates, local, state and national, and have asked for replies. These replies, when received, are published in the newspapers. We have kept a complete file of all publicity, letters received and clippings bearing on the whole question of socialized medicine, so that they are available for reference and other work.

This, in brief, is our feeling and our plan of attack on this problem. We bring it to the attention of the House of Delegates because we feel that the time to begin is now and that the place to begin is with each physician in his own locality, with his own patients and by his own county medical society. We wish to urge that the various state medical societies appoint a coordinator to see that various county medical societies carry on this work. We would likewise suggest that the American Medical Association allocate from its treasury sufficient funds to pay representatives in every state to visit each county medical society and to advise them further how to proceed. We wish to suggest two other things:

1. That we as a body stress the political significance of supporting those men who are candidates for office or present office holders who will oppose in the next session of Congress or state legislatures any plan for socialized medicine in the administration of which the physician is not given the controlling voice. We feel that if passage of legislation not favorable to us can be delayed for a while we can formulate

for ourselves plans which will meet the requirements of ethical medical practice.

2. That, if necessary, every physician in the United States should be assessed a certain amount, the collection of which is to be undertaken by the component medical societies, to be used in forms of publicity, in paying traveling representatives or in financing necessary lobbies.

In conclusion, we feel that in presenting these plans we should likewise pass on to other bodies contemplating similar publicity certain mistakes which we made and certain facts which we learned:

1. We feel that Dr. Leland's article, while an excellent one for the medical profession and for the better educated members of the laity, is perhaps not couched in simple enough terms to be as understandable as it might be; consequently we would suggest that, if this article is to be used, it be further simplified and explained before it is reprinted or that another article be written in the language of the laity.

2. We have found that tremendous numbers of individuals, including dentists, lawyers and other professional persons, are not even superficially conversant with this issue.

3. We likewise learned that too many newspaper articles published at one time or in a series worked against us, in that continued repetition destroyed reader interest.

4. We discovered that perhaps our best plan of attack was to each individual patient, by explanation in understandable terms, and we found that it required intense personal interest on the part of the physicians to keep "hammering" at the proposition day in and day out.

5. We lastly discovered that we must expect a certain amount of opposition from within our own ranks from those who are practicing in a group "under an umbrella," so to speak. We feel that this group can be brought into our way of thinking if we will provide workable plans in each community in order to care for those in the lower income groups and thus enable these physicians to have better remuneration.

In summing up, therefore, we wish to thank you for the opportunity to present our plan with its reasons, its mistakes and its results, and to make a plea that your component medical societies follow some similar plan in making this a nation-wide educational campaign against the proposed regimentation of medical practice.

Recommendation on Cooperation for Needed Improvements in Care of Indigent

Dr. A. T. Gundry, Maryland, presented the following recommendation, which was referred to Divisions 2 and 3 of the Reference Committee on Consideration of the National Health Program:

WHEREAS, The proposals of the National Health Conference recently held in Washington, which should be primarily a medical problem, are in the light of present conditions primarily an economic problem; and

WHEREAS, It was no doubt thought by those who first made these proposals several years ago that the financial conditions of the country would improve and permit these efforts, but instead taxes are increasing, the budget is independently out of balance, the national debt is increasing, business is uncertain and uneasy, and the present management of social security matters does not establish confidence; and

WHEREAS, The proposals of the National Health Conference would entail the expenditure of nearly a billion dollars a year, adding to the difficulties above mentioned; therefore be it

Resolved, That while this organization wishes to cooperate in any measures for the improved health of the country, it feels that the need for such legislation as recommended is not yet proved and in the present financial condition of the United States it is unwise to attempt such a costly problem as outlined; and be it further

Resolved, That this organization recognizes the need for development of many phases of the health problem but feels that the development should be gradual and approximately on a "pay as you go" basis with a balanced budget; therefore it is

Recommended, That the federal and state governments and the American Medical Association cooperate to their fullest ability to bring about the most needed improvements in the care of the indigent and medically needy but that the elaborate program proposed be abandoned for the present.

A motion to set a time limit for the introduction of new business at this special session was tabled.

Proposals Concerning Scope and Methods of Governmental Participation in a National Health Program

Dr. H. L. Snyder, Kansas, introduced the following proposals, which were referred to each of the five divisions of the Reference Committee on Consideration of the National Health Program:

Health is fundamental for the happiness and welfare of any people. The fact that neither the federal nor state governments have ever had a definite policy in this important field has led us to set forth our proposals on this subject. Governmental participation in the solution of such problems should be carefully planned and the limitations of such participation clearly defined.

In arriving at our recommendations we accept certain premises which we believe are pertinent and fundamental, among them the following:

1. The economic situation of an individual or group has a definite relationship to health and consequently to medical needs and medical service. Poverty and disease notoriously go together. Attempts to service the health of the poor without attention to the fundamental economic situation which results in poor food, inadequate clothing and shelter and the mental stress accompanying such conditions are sure to fail.

2. The attainments of medical science, including dentists, pharmacists and nurses, in the United States are not excelled in any country in the world. No people in the world have access to better medical care whether measured qualitatively or quantitatively, than have the people of the United States.

It follows that any proposed changes in our present system of medical service must improve present conditions and must not merely replace shortcomings now existing with new evils. At all times contact must be maintained with reality, and experience is a safer guide than theory.

3. Experience elsewhere has demonstrated that any solution of the problems of medical care that even approaches medical socialism is fraught with dangers that are both grave and certain. Some of such dangers are:

(a) The lowering of standards of medical practice and the retardation of the progress of medical science.

(b) The imposition of an intolerable tax from which inferior medical service results.

(c) In general, the encouragement of the tendency to socialize all industries and professions as a panacea for the ills of the body politic.

With the foregoing fundamental considerations in mind, we proceed to our discussion.

The problems incident to the preservation of health and provision of medical care naturally divide themselves into two categories. There are first those problems usually referred to under the terms "public health" or "preventive medicine," and second those which involve the health of the individual citizen and his ability to secure good medical care.

PUBLIC HEALTH AS A NATIONAL PROBLEM

In general, the question of public health concerns local governments, municipal, county and state, more directly than it does the federal government, although the latter is intimately and properly concerned with some of its phases. Contagious disease recognizes no state boundaries and the results of criminality produced by physical and mental disabilities are felt throughout the nation. The welfare of mothers and newborn babies continues to be a national problem of major importance. The present program for child health and maternal welfare is susceptible of extension on a nation-wide scale through complete organization of the 3,000 counties of the nation.

The control of the venereal diseases is another problem which must be met. Means must be provided to make our present knowledge generally applicable and the known diagnostic and curative procedures generally available. The far-reaching program for control of the venereal diseases which has been inaugurated by the United States Public Health Service must be continued and enlarged as experience indicates the best methods of attack.

We are convinced that as advances in medical science and knowledge take place, increased governmental participation in making them practically applicable in the field of preventive

medicine will be clearly indicated and will receive the support of the medical profession and the public. We record our conviction here that the medical profession because of its training and experience is best fitted to furnish leadership in all movements for improvement of the health of the people. This place of leadership must be recognized and no paternalistic or bureaucratic control permitted to destroy the freedom and initiative of that profession.

A comprehensive program for the prevention and cure of disease such as we envisage must include the cooperation not only of the federal government with state and local governments but of all governmental health officials with private physicians throughout the length and breadth of the land. Such a program is in harmony with our determination that private enterprise in business and the professions must be preserved, encouraged and fostered.

ORGANIZATION OF HEALTH ACTIVITIES WITHIN THE FEDERAL GOVERNMENT

The federal government contains now within its structure numerous departments and bureaus which carry on activities related to health and medical care. The separate and uncoordinated administration of these numerous activities promotes waste and inefficiency. It appears logical and necessary that all activities which concern health and medical care except those of the Army, the Navy and the Veterans' Bureau should be concentrated within one department of the federal government. It is our belief that this desirable object can be accomplished without the creation of any new departments or bureaus. Although it may seem theoretically desirable to establish a new department with a cabinet head to control and direct activities of such vital importance as those connected with the health of the people, it is our belief that economy in government is of such fundamental importance in the years immediately ahead that concentration and coordination should be our object instead of expansion. The excellent organization and the record of achievement of the United States Public Health Service points to it as the governmental bureau in which all health activities of the federal government should be concentrated. It is our belief that such a concentration will promote efficiency, secure coordination of activities and promote unification of our national health program.

The necessity for drastic economy in administration of government renders it highly inadvisable to create new departments of government in the immediate future. For this reason we do not recommend at this time the creation of a Department of Public Welfare which has been lately advocated in some quarters. If and when such a department is created its duties would be so manifold that no attempt should be made to include within it a bureau of public health. It is especially undesirable that the care of the health of the people should be relegated to a secondary place within a department with such vague and unrelated activities as are described by the terms "social security" and "public welfare."

We are especially impressed with the necessity for a unified program to replace our present uncoordinated and haphazard methods of dealing with health matters through the federal government. Large appropriations of funds are made from time to time for specific purposes without due regard to the entire health program. Veterans' and other hospitals are often established out of purely political considerations; and the federal government has a tendency to assume duties which should be largely local and which should have only a minimum of federal assistance.

The time has arrived when, after exhaustive study, the place of the federal government in health activities should be defined, a definite policy adopted and an efficient organization established.

MEDICAL CARE OF THE INDIVIDUAL CITIZEN

The second sphere of proper governmental concern with public health embraces the problem of insuring good medical care to every citizen regardless of his economic status. That such medical care should be available to all is obvious whether the matter be considered from the point of view of pure altruism or from that of a selfish desire to protect one's own health. Disease prevalent in the underprivileged groups knows no social or economic boundaries.

The problem is enormously complex because it is intimately bound up with all the social and economic problems that harass modern civilization. It is therefore impossible to offer any practical single solution. Although the problem is real and must be faced, it should be approached in the light of one of the fundamental proposals which we have already stated, namely that European experience has demonstrated that experiments in medical socialism are dangerous and give rise to far-reaching evils which are much worse than those we are attempting to cure.

It is our belief that there is an American way to solve these problems whereby we may preserve a maximum of individual freedom and initiative and utilize a minimum of governmental or bureaucratic control.

With respect to his ability to command adequate medical care for himself and his dependents, the citizen falls into one of three groups. There are those whose economic resources are equal to all demands, ordinary and extraordinary; second, the great middle class, generally able to meet ordinary demands, but likely to be economically swamped by prolonged or high-cost illnesses; and third, those living at or below a bare subsistence level who cannot pay for medical care at all. The first group needs no aid, governmental or other, and may be dismissed from further consideration. The proper spheres of governmental activity in helping the two remaining groups with their medical problems are clearly divergent and demand separate consideration.

MEDICAL CARE FOR THE MIDDLE INCOME CLASS

In our opinion, every consideration of a sound governmental policy indicates that government should approach the problem of the middle class, which comprises the great bulk of self-supporting American citizens, determined to avoid paternalism. The keynote of its policy should be to help the citizen to help himself.

We note with approval the nation-wide survey being conducted by the American Medical Association through its constituent state and component county units to determine the medical needs of all the people. We are hopeful that out of this survey may come such a definite knowledge of the facts that inadequacies in present methods may be corrected in every local community.

We approve the principle of hospital service insurance which is being widely adopted throughout the country. It is susceptible of great expansion along sound lines and to many groups of the population which it has not yet reached. Experience in the operation of hospital service insurance or group hospitalization plans has demonstrated as a fact, what was clear to many before they were organized, that these plans must confine themselves to provision of hospital facilities and must not include any type of medical care. Within their limitations they are very helpful to the people of employed groups in meeting that part of the costs of illness entailed by hospitalization.

In addition to insurance for hospitalization we believe it is practical to develop insurance plans to cover, at least in part, the costs of prolonged or expensive illness. Agencies set up to provide such insurance must be under rigorous governmental control to insure their soundness and financial responsibility, just as insurance companies are everywhere regulated. We are, however, opposed to governmental subsidy of, or other financial participation in, their activities. We believe that general experience has proved beyond doubt that unsound cooperative methods of voluntary health insurance invariably lead to adoption of compulsory health insurance with its inevitable accompaniment of government subsidy.

DISCUSSION OF COMPULSORY HEALTH INSURANCE

We are aware of the fact that most European nations have adopted some variety of compulsory health insurance under state control. Study of the operation of these systems in various countries and examination of the proposed laws for compulsory health insurance introduced into the U. S. Congress and the legislatures of the states bring out the following facts:

1. Compulsory health insurance is a system of taxation which requires a wage tax, a payroll tax and a government subsidy derived necessarily from general taxation.

2. There is much testimony to the effect that the medical care received by the beneficiaries of the compulsory insurance is of an inferior quality as compared with the average prevalent in the United States.

3. Compulsory health insurance requires for its operation a large administrative force with consequent development of bureaucracy and an administrative expense far beyond any possible value in medical care received by the people.

4. A compulsory health insurance system results in a high degree of governmental control of both the physician and the patient.

For these reasons we are not willing to foster any system of compulsory health insurance. We are convinced that it is a complicated, bureaucratic system which has no place in a democratic state. It would undoubtedly set up a far-reaching tax system with great increase in the cost of government. That it would lend itself to political control and manipulation there is no doubt. Great difficulties have been found in the practical application of the old-age pension and unemployment insurance laws and it is generally admitted that they are relatively simple operations compared with a system of compulsory health insurance.

In every nation in which compulsory health insurance has been made a part of the national economy there has been a steady, continuous decline in the democratic features of the government.

We recognize the soundness of the principle of workmen's compensation laws and recommend the expansion of such legislation to provide for meeting the costs of illness sustained in industry.

We repeat our conviction that there are sound types of insurance which may assist the middle income group to finance their sickness costs without state subsidy. Further development of group hospitalization and establishment of insurance plans on the indemnity principle to cover high-cost illnesses will go far in the solution of these problems.

MEDICAL CARE OF THE INDIGENT

The proper sphere of governmental activity with respect to the care of the indigent falls into an entirely different category from that of the care of the middle income group. It is almost entirely a problem for local governmental units. Heretofore it has been met locally largely through the establishment of tax supported hospitals in which are treated the more serious illnesses of this group—and those that constitute a public health menace. Some further resources are provided by the free clinics of private hospitals mainly supported by the contributions of charitably disposed citizens.

In few, if any, localities is there any service offered even approximating adequate home medical care for the more or less minor illnesses of this group, or providing mechanisms to make the vast resources of modern preventive medicine available to them. Whether considered from an altruistic point of view or from that of the public health, it is obvious that such provision is necessary.

As a matter of fact, immemorial usage has left the care of the indigent largely to the freely given and unremunerated service of the medical profession.

We hold that such care is fundamentally a proper concern of the state and should be adequately supported through general taxation. In no other way can the care be given that is necessary to conserve the health of the individual and to prevent his becoming a menace to the health of others.

It is plain to us that in carrying out such a tax-supported system we must conserve all of the resources of our long-established system of medical care through private practitioners of medicine. It is our firm belief that government (preferably local government) should provide the funds needed for the medical care of those who cannot care for themselves but we just as firmly believe that the function of providing the medical services resides in the medical profession and should remain there. Similarly, whenever private community hospitals have the facilities for care of the indigent they should be utilized to the fullest possible extent before new government hospitals are provided.

We are aware of the dangers that may be involved in the distribution of the funds necessary to carry out a program

of state care of the medical needs of the indigent. We therefore advocate the utmost caution in devising methods for such distribution which will prevent these funds from being subject to political control. Communities should study this problem, in consultation with local medical and welfare organizations, with the firm intent to utilize to the fullest possible extent existing agencies, and to avoid the menace of setting up expensive bureaucratic machinery calculated to absorb a large share of the public funds primarily intended for medical care.

We summarize our position on health and medical care as follows:

1. The United States has made great progress in the past, and the quality of medical care now provided is of a very high grade. We wish to see those methods and practices perpetuated and improved which have brought us to the present high plane.

2. We wish to see established a well coordinated program in state and nation for the control and elimination of infectious disease and for the improvement of maternal and child health.

3. We advocate concentration of the health activities of the federal government within the structure of the present United States Public Health Service. We believe that this is in accord with economy in administration and added efficiency without materially increasing the tax-load of the people.

4. We believe that the solution of the problem of providing adequate medical care for the great middle class of the population should be left to the citizens and medical profession of local communities. They alone know and understand their varied requirements. Such endeavors should receive the most sympathetic support from government in every legitimate way that is free from bureaucratic control.

The insurance principle should be adopted for this class where it is sound and resolutely rejected where it is economically unsound and where it promotes paternalism in government or medical socialism.

5. We advocate recognition of the principle that the complete medical care of the indigent is a function of the community, medical profession, dental profession, pharmacists and nurses and that such care should be organized by local government units and supported by tax funds.

Since the indigent sick constitute a menace to the entire population, we recognize that the necessity for state aid may arise in poorer communities and the federal government may need to participate when the state is unable to meet emergencies.

6. Great progress has been made in the United States in the reduction of morbidity and mortality among all classes of people and in all matters pertaining to public health and medical service, and the quantity and quality of medical care now provided is of very high grade. We wish to see these methods and practices perpetuated and improved which have brought us to this present high plane.

7. We wish to see established a well coordinated program in the various states in the nation for improvement of food, housing and the other environmental conditions which have the greatest influence on the health of our citizens. We wish also to see established a definite and far-reaching public health program for the education and information of the people in order that they may take advantage of the present medical service available in this country.

8. We repeat that the solution of the problem of providing adequate medical care for the great middle class of the population should be left to the citizens and medical profession of local communities. They alone know and understand their varied requirements. Such endeavors should receive the most sympathetic support from government in every legitimate way that is free from bureaucratic control.

9. We believe that public health and medical service as a whole will suffer and deteriorate through the application of regimented and governmentally controlled methods of medical practice, and we are convinced that the public health of the nation can best be maintained through continuation and advancement of the present individualistic practice of medicine.

Missouri Plan for Medical Care of All the People

Dr. Carl F. Vohs, Missouri, presented the following plan, which was referred to each of the five divisions of the Reference Committee on Consideration of the National Health Program:

It is a little over four years ago that the Missouri State Medical Association began to study the sociohealth movement in this country and the accomplishments of such movements in European countries.

We came to the conclusion that compulsory health insurance with cash benefits is not a desirable solution to our problems. The one outstanding problem before the medical profession today from the standpoint of the curative treatment of disease is the development of an adequate medical service for all persons at a cost which can be met by them in their respective stations in life. It is in answer to this problem that the Health Security Administration of the State of Missouri is being planned and developed.

Following the survey that is being made of the medical needs, the state is to be divided into economic units. Each unit will support in a coordinated program:

1. A Group Hospitalization Plan.
2. A Medical-Dental Service Bureau.
3. A Central Registration Bureau.

Representatives from the boards of management of each of these bureaus will make up the Health Security Administration of the economic unit. A representative from each Health Security Administration will sit on a state board to be known as the Health Security Administration of the State of Missouri.

It is planned that this Health Security Administration of the State of Missouri will be in control of all plans and monies established by federal grants-in-aid. It will have the right to assist local economic units in the building of needed hospitals and clinics from state and federal funds.

The respective local boards are made up of medical men, dentists, hospital representatives and the public. If we must have a national health program, such an administration could handle it most safely and most sanely and would meet all the requirements of the Technical Committee in its suggestions and plans for a unified system of state health.

We have divided the people into four classes. The upper 25 per cent of the people can pay for all medical, dental and hospital care at all times. The second 25 per cent can with some assistance pay reasonable fees for health care. For this group we have arranged the Medico-Dental Service bureau for the postpayment of their medical, dental and hospital bills. These bills are to be liquidated in a year's time. For this group we also have inaugurated group hospitalization which at a cost of 75 cents per month per individual, \$1.25 per month for husband and wife, and a maximum of \$1.50 a month for any sized family, pays for thirty days a year for each of them in any of our hospitals. If they stay longer than thirty days, one third of the bill for six months is paid. The average stay in the past two years has been 9.7 days.

For the third group of 25 per cent of our population, the two bureaus are of great service. Group hospitalization will take care of their hospital liability, and their medical and dental bills must be scaled down to meet their ability to pay. For the lower strata of this group, which of course varies greatly in number in direct ratio to our depressions and recessions, the third bureau, the Central Registration Bureau, is intended. The patient will pay what little he can for his hospitalization if he is not a member of Group Hospitalization, and the remainder is to be paid out of United Charity Funds at an agreed per diem cost. The medical care after proper investigation of these patients will be given gratis by the medical profession. It is hoped after the indigent load of the community has been definitely established by the Central Registration Bureau to work out a prepayment cash payment plan for medical and dental care for this whole group.

The last group of 25 per cent of our population will always be the responsibility of the community and their care should be paid for on a per diem basis by the United Charities as they are vouched for by the Central Registration Bureau. If the funds of the United Charities are not sufficient to liquidate this liability, then city, state and national tax funds must

subsidize the program. This will fit in well with the national health program.

If the medical and dental burden for the care of this group becomes too great, then plans like the Los Angeles County Plan and the Oakland (Mich.) Plan will be instituted. These plans pay for the care, medical, dental, and other, out of tax funds. Again we can use federal grants-in-aid.

We in Missouri feel that this is a "state system" such as is recommended by the National Health Conference and meets the suggestion that "The role of the federal government should be principally that of giving financial and technical aid to the states in their development of sound programs through procedures largely of their own choice."

It is a state system establishing and meeting all the needs of all counties in the state; it is voluntary in every aspect and without political control.

Resolution on Change of Medical Care for the People

Dr. Charles A. Dukes, California, read a resolution on Change of Medical Care for the People, which, the Chairman ruled, was not germane to the call.

Recommendations from Medical Society of the State of Pennsylvania

Dr. Francis F. Borzell, Pennsylvania, presented the following summary from the Medical Society of the State of Pennsylvania, which was referred to the Reference Committee on Consideration of the National Health Program and its respective divisions:

Following the call issued by the Board of Trustees of the American Medical Association for a special meeting of the House of Delegates to be held in Chicago beginning September 16, for the purpose of considering the program so widely publicized after the July 18-20 meeting of the Interdepartmental (Federal) Committee to Coordinate Health and Welfare Activities in Washington, the following steps were undertaken by the Medical Society of the State of Pennsylvania:

The attention of the officers of all component societies was immediately drawn to the call, the date of the meeting, the names of the members most likely to represent the state society at the special meeting in Chicago, the source of a full report of the National Conference, recommendation that individual members convey their impressions to individual delegates from the Medical Society of the State of Pennsylvania, an abstract of the recommendations of the Federal Technical Committee was distributed to all prospective Pennsylvania delegates, to the members of the state society Committee on Public Health Legislation and representatives of the Committees on Public Relations and Medical Economics, and to the members of the Board of Trustees of the state society, who had in the meantime called a special meeting of all the above mentioned, to be held at the state society's building in Harrisburg, September 7.

At a meeting of the Public Health Legislation Committee held the morning of September 7, there was a generous attendance of delegates, state society officers and representatives of other state society committees. At the joint meeting held under the sponsorship of the Board of Trustees during the afternoon, there was a larger attendance and a full discussion of not only the recommendations of the Federal Technical Committee but also the conclusions of the morning conference held under the auspices of our Committee on Public Health Legislation.

As a result of all the foregoing, the delegates who will represent the Medical Society of the State of Pennsylvania at Chicago on September 16 were given the following for their most careful consideration in the light of that which may develop during the deliberations of the special session in Chicago:

1. Urge again more especially because of the recommended expansion of health services under federal sponsorship the creation of a federal Department of Health represented in the President's Cabinet by a Secretary of Health, authorized to coordinate all health activities which are now scattered throughout various other federal departments. This department should maintain a rigid civil service or merit system thereby insuring to the public continuous and uninterrupted ever-improving health service easily available but entirely removed from the

influence of partisan politics. This can be accomplished well within the province of a truly democratic form of government.

2. Advise the calling of further conferences of the entire national group for the purpose of considering in review the actual necessity of the recommended expansive program which might be replaced by proposals to improve the present facilities for the medical care of the indigent on a much less extravagant basis. The state of desired perfection in health will in all probability never exist under any authority. Nevertheless, we commend the advantages of logical, reasonable expansion of existing health and sickness service facilities such as may result from coordinated study and activities under the sponsorship of the United States Public Health Service and the direction of all licentiates who are qualified and legally responsible for the medical care of the citizens of this nation in cooperation with governmental authorities.

3. As the necessity for expansion of this program may be developed and approved, advise (a) the maintenance at all times of definite assignment of proper functions for the care of the indigent sick with (b) equally definite functions proposed for such service to any other social or economic group.

4. Provide each member of the Congress of the United States with a copy of all plans proposed in order that each may discuss with his constituents the necessity for the proposals, as well as the ability of the taxpayers to pay for same.

In the development of such plans for sickness service to the low income group of the population as were recommended by the National Health Conference, they should be supervised entirely by the various licentiates involved in the delivery of the service and should be maintained at a level to insure the best quality of health service so as not to justify intervention by political groups. This can thus be accomplished, at the same time maintaining a true democracy in our form of government.

5. Request the American Medical Association to maintain representation in Washington helpful to Congressmen and Senators regarding the medical profession's point of view on all health legislation and also at the same time keeping the constituent state medical societies properly informed on activities in the federal Congress with appropriate suggestions as to the kind of information which should be conveyed to the members of Congress from each state by the proper representatives of the given state or district medical societies.

The problem of the health of our nation having been precipitated into the midst of political consideration, it must be for the present handled by the professional groups concerned by appropriate methods.

6. Alternatives to overly expansive and expensive governmental proposals for the development of health programs must be offered by the medical and allied professional groups and constructive and cooperative effort must be continuously maintained if the American public is to consistently receive an efficient health service.

7. Carefully chosen, nonconfusing health information, free from partisanship, should, through each county medical society, be projected into the life of the various communities. The proper officers of each county society should seek opportunity for representation on the programs of as many social clubs and public forums as possible. Information distributed should deal with the various phases and relations of the health of the public and of sickness service in a uniformly clear yet concise manner.

In addition to the foregoing, presented without definite instruction but for the guidance of the Pennsylvania delegation, the Board of Trustees requested that the following resolution, referred to the Board by the Dauphin County Medical Society, be conveyed to the House of Delegates of the American Medical Association in special session at Chicago:

WHEREAS, The Social Security Act of Congress made possible the creation of an Interdepartmental Committee to Coordinate Health and Welfare Activities; and

WHEREAS, The Chairman of said Interdepartmental Committee convened a session known as the National Health and Welfare Conference; and

WHEREAS, Various proposals there discussed are economically extravagant, sociologically impracticable, scientifically stifling and professionally deteriorating; and

WHEREAS, The President of these United States did publicly proclaim that a "coordinated national program of action" is imperative; be it

Resolved, That the Dauphin County Medical Society, through its duly constituted State Medical Society, does hereby petition the American Medical Association:

(a) To announce, publish, proclaim and promulgate by commercial radio, press release, paid advertisement and public acclaim such specific methods and measures as its duly constituted officers and its House of Delegates recommend as practicable and expedient, within scientific and economic limits, in the prevention of illness and the conservation of the health of the citizens of the nation, and

(b) To combat, oppose, contradict and amend, by the same means, such idealistic, fanciful, impracticable and extravagant schemes as will rebound eventually to encourage malingering, stifle initiative, retard progress and disrupt the traditional physician-patient relationship; and be it further

Resolved, That the proper representatives of the American Medical Association be empowered also to accept voluntary contributions from individuals and organizations, lay and professional, who may choose to assist in underwriting the expense incident to this proposed effort.

The preceding is a very brief summary of conclusions arrived at in conferences held at special meetings at 230 State Street, Harrisburg, the morning and afternoon of September 7, conferences being attended by eleven of the twelve members of the Board of Trustees of the Medical Society of the State of Pennsylvania, thirteen of the fifteen members of the Committee on Public Health Legislation, representatives of the State Society Committees on Public Relations and Medical Economics, the Editor of the *Pennsylvania Medical Journal*, and by seven of the eleven delegates from Pennsylvania who have agreed to serve at Chicago.

Those receiving this summary are requested to indicate on the enclosed post card, by return mail if possible, their reactions to the report as herewith submitted.

EDGAR S. BUYERS, Chairman.

WALTER F. DONALDSON, Secretary.

Sept. 12, 1938.

Plan from New Jersey for Medical Care of the Indigent

Dr. E. R. Mulford, New Jersey, presented, without reading, the following plan, which was referred to Division 3 of the Reference Committee on Consideration of the National Health Program:

From the President to the Trustees:

The National Health Conference held in Washington, D. C., on July 18, 1938, was the most significant and far reaching medical event in American history, although it was neither conceived nor conducted by medical men. The Medical Society of New Jersey is in sympathetic accord with the broad objectives and humanitarian purposes which guided that conference. We believe that we are our brother's keeper. We agree that preventive health services in the United States are inadequate; that more hospital beds are needed, particularly in rural areas; that the distribution of medical care has not kept pace with the progress of medical science so that all people who want medical care do not always receive all that science has to offer, and, finally, that the economic burdens of illness fall heaviest on the poor who are least able to bear them. With these broad principles we fully agree.

As a sequel to the National Health Conference the next Congress will be asked to appropriate \$850,000,000 with which to begin proposed reforms. This sum is to cover the first year only and will be distributed to local areas that can match federal funds dollar for dollar. The wisdom of this we question. Areas most in need are least able to raise their quotas. \$850,000,000 is only the beginning. This will be increased to \$2,600,000,000 a year if all phases of the plan are adopted. The Medical Society of New Jersey urges deliberate, thoughtful consideration of the five phases of the plan, which are in brief as follows:

1. Expansion of public health in maternal and child health, tuberculosis, venereal diseases, malaria, pneumonia, cancer, mental hygiene and industrial hygiene. The annual cost will be \$200,000,000, one half of which is to be furnished by the federal government.

2. Expansion of hospital facilities by providing 360,000 extra beds in general, tuberculosis and mental hospitals and by the establishment of five hundred health and diagnostic centers in inaccessible areas at a cost of \$146,500,000 spread over a ten year period. One half of this cost is to be met by federal

funds. Here again the difficulty lies in the fact that inaccessible areas cannot raise the other half.

3. Medical care of the medically needy by federal grants for the care of the members of the indigent and low wage groups at a minimum annual cost of \$400,000,000, half of which is to be furnished by the federal government.

4. Federal aid to states in the development of programs of their own choice for self-supporting persons who are burdened by unexpected illnesses and that funds be secured from general or specific taxes and insurance contribution from the beneficiaries.

5. Insurance against wage loss during sickness along the lines of unemployment compensation.

The total cost per year of local, state and federal government will be \$850,000,000 for proposals 1, 2 and 3. Proposals 4 and 5 are not included because they require additional taxes and insurance. It is estimated that the cost of insurance will involve 4 to 4.5 per cent of the income of the entire population so that the total estimated cost of the five proposals is \$2,600,000,000 a year.

While the humanics are commendable, the mechanics are vague and incomplete and some of the specific recommendations are actually dangerous.

It is, of course, readily apparent that problems as vast as those under consideration, with ramifications and implications the end of which no man can clearly foresee, are not to be solved efficiently or with safety to the body politic merely by illimitable appropriations. Sickness and its control, as well as the prevention or amelioration of its aftermath, require more than the mere access to money. Unless such monies are wisely expended by and under the direction of those whose function it properly is to utilize and direct appropriate measures, the program fails.

Much has been said—and not always either well or wisely said—of the cost of sickness; indeed, this motif furnishes much of the driving force behind the program.

But an adoption of the plans of the National Health Conference in toto must inevitably increase the cost of sickness by the necessity of an army of administrators and the equally inevitable red tape inseparable from such administration. In fact, in countries where socialized medicine has been adopted, the cost of administration has equaled the cost of medical care. This cannot be explained on the assumption that the program is new and that new administrations must feel the way and learn by experience, which is always costly. Costly experience has shown the world over that bureaucracy tends to expand and to perpetuate itself; never the reverse.

That the quality of medical care will be lowered is equally inevitable. One need cite only the "lodge doctor" as illustrative of the deleterious effect of the removal of the competitive stimulus and the stultifying influence of a political atmosphere. Under the present system more than one half of the doctors of New Jersey have taken postgraduate work within the past five years; during this time, not a single "lodge doctor" has taken a postgraduate course.

Federalized medicine is inseparable from an ultimate politicalized medicine, which then becomes the instrument of politicians and the health of the people a political weapon in the hands of whatever political party happens to be in power. Inefficient medical care will be the inescapable concomitant of medical regimentation.

There are those who profess to believe that federalized medicine and regimented medicine need not be synonymous and that the one need not necessarily imply or lead to the other and that both can be divorced from political control. With this in view we are reluctantly compelled to disagree. It is, we believe, inconceivable that a program conceived on so vast a scale, to be financed by such extraordinary expenditure, can ever be divorced from its political possibilities and implications. We do not believe that it can be established without bureaucracy or carried on without medical regimentation, nor are we confident that either the one or the other, or both, are in the best interests of those for whom the program is advocated.

For it cannot be successfully denied that if, like all men, politicians are human, they are also all too often inhuman in the avidity with which they tend to subordinate all else

to political expediency and the perpetuation of political power and control.

The sum of \$850,000,000 is based on the assumption that one third of the population of the United States is now without adequate medical care. We are not assured of the correctness of this assumption, which is based on the fragmentary study in 1937 by the United States Public Health Service of only 800,000 families scattered here and there throughout the country.

For the past eight months the various county medical societies of the United States have been conducting a survey of the present supply of doctors, dentists, druggists, nurses, hospitals and all other institutions, departments and agencies, private and public, which are concerned with the health of our people. These surveys are not yet completed. No one knows what they will reveal.

However, in New Jersey a study of the preliminary reports of ten counties show that less than 5 per cent of those who want adequate medical care are unable to obtain it and the difficulty lies in the fact, not that it is not available, but that they do not know where to obtain it. In July of this year the various newspapers and radio stations of New Jersey carried an appeal urging every one who knew of a case that for any reason could not receive adequate care to notify the office of the medical society in Trenton. Repeated appeals have resulted in the receipt of thirty-nine letters, all of which have been referred to the county societies where they belong. The population of New Jersey is four million.

It is possible, of course, that not all the four million population of New Jersey were reached by these appeals and equally possible that not all who read or heard them responded. But that so few responded casts justifiable doubt on the assumption that one third of our people are unable to secure adequate medical care and suggests also that the proportion indicated by this response implies a less acute situation than that hitherto assumed.

The Medical Society of New Jersey urges a careful consideration of the effect on business of the addition of an annual astronomical item of \$2,600,000,000 to the already tremendous tax load. We are not economists, and neither economists nor business men, including manufacturers, employers or representatives of the taxpayers, were present at the National Health Conference or had any more voice than those present at the Conference by invitation. We believe that before levying such a stupendous tax the question should be answered "Will not the huge tax levy destroy business, which is the only source of tax funds?" If so, what then is to become of the helpless?

While the Medical Society of New Jersey counsels caution, we are not obstructionists who believe that the present system is perfect. But America must not mistake change for progress. Long before the National Health Conference was conceived, the Medical Society of New Jersey had developed a positive constructive plan which we believe is sound, economical and free from the dangers of the plan to be proposed to Congress. This plan briefly is as follows:

We propose to lower the cost of illness by the application of sound economic principles in the distribution of medical care by protecting the public against the incompetent and the mercenary within the profession, against ignorant cult practitioners and fraudulent "patent medicines," for which many millions of dollars are foolishly and wastefully expended.

We propose to lessen the unpredictable burden of medical and surgical catastrophes by developing measures for deferred payments and hospital insurance.

We propose to protect the people, rich and poor alike, from costly impersonal, inefficient, politicalized medicine by preserving for liberty loving Americans the inherent right to engage physicians of their own choice. This system has stimulated the greatest medical progress ever known to mankind. To destroy it, rather than to correct its imperfections, would be an irrational public disservice.

We propose to preserve this American system with its free choice of physicians for the low wage group by adjusting medical fees to income, thus preventing pauperizing of patients in clinics, and preserving for them self respect, self reliance and independence.

We propose to secure state aid for the care of the indigent and at the same time to preserve for them the free choice of physicians. In the past, the cost of their medical care has been added to the medical and hospital bills of pay patients. The rapid increase in the number of indigents makes the continuance of this inequitable practice impossible. The care of the indigent is the duty not of pay patients alone but of all the people. Without state subsidy for the indigent, it is impossible to maintain good care for the low wage group at a lowered cost. With state subsidy for the indigent supervised and directed by the medical profession itself instead of politicians it is possible not only to render efficient service to the low wage group but to preserve for the indigent the personal and sympathetic care of physicians of their own free choice. This is not an untried theory but an economical plan proved workable in New Jersey by the original Emergency Relief Administration during the years of 1934 and 1935. Under this plan, the poor applied to the local relief office, where orders were issued for food, fuel, rent and medical care. A list of local doctors was posted. From this list the poor made their own free choice. The list was kept free from irregular, incompetent and mercenary doctors by the state and county medical societies, which were put, as it were, on their honor. The list included, not doctors who basked in the sunshine of political preferment, but all doctors who were willing to keep adequate records and to serve at reduced fees. And they were remunerated by relief funds at the rate of one dollar for each office visit and two dollars for each house call.

The first step in the proposed government reform of the practice of medicine is to expand public health services in maternal and child health, tuberculosis, venereal diseases, malaria, pneumonia, cancer, mental hygiene and industrial hygiene. If Congress appropriates the money, there will be no difficulty in expanding public health services. However, mere expansion of public health is not the goal. The goal is to lessen maternal mortality, to improve child health, to decrease the incidence and ravages of tuberculosis, venereal disease, malaria, pneumonia and cancer and to improve mental and industrial hygiene. Experience in New Jersey has proved that the goal can be reached without the expenditure of huge sums in expanding public health. As an illustration let us consider maternal welfare.

When the Social Security Act became a law, the federal government wanted to send full time field physicians in maternal welfare into New Jersey, but reluctantly, with its tongue in its cheek, turned over the Social Security funds to the state department of health. Instead of importing full time field physicians, each county medical society was permitted to recommend, the state medical society was permitted to approve and the state health department finally selected one field physician from each of the twenty-one counties. The total bill of all these part time field physicians last year was less than \$13,000. Our own field physicians have the confidence of the doctors and the laity at home. They visited every physician in the state who is doing maternity work. They promoted postgraduate study, distributed literature and checked up personally on every maternal death. The Social Security funds also paid for consultations in maternity cases at the rate of \$5 each, \$10 for operative delivery. In addition, these funds remunerated trained nurses \$5 for assistance during delivery. These monies were expended only on members of the low wage or indigent group on the recommendation of the attending physician.

What has been the result? Three years ago the maternal death rate in New Jersey was more than 5 per thousand. It dropped each year so that now it has reached the remarkable figure of 3.2, one of the lowest maternal mortality rates in the United States, indeed in the whole world. This could never have been accomplished by any Public Health Service alone. It needed the wholehearted cooperation of the doctors, nurses and welfare agencies as well. It would have been possible for the long arm of the federal government to reach into New Jersey and with the expenditure of huge sums of money build a large and expensive maternal welfare department of public health. But, no matter how much money is squandered, without the cheerful and willing cooperation of the doctors and nurses

themselves, such remarkable results would never have been secured.

The same principle applies to child health, tuberculosis, venereal disease, malaria, pneumonia, cancer, mental hygiene and industrial hygiene. The Medical Society of New Jersey and the Public Health Department have or are setting up the same sort of machinery to combat every one of the diseases, except one, for which the federal government would ask public health expansion. That exception is malaria, and malaria is not much of a problem in New Jersey.

Let us keep our heads in the clouds and our feet on the ground.

Recommendations from the Medical Society of New Jersey

Dr. Wells P. Eagleton, New Jersey, submitted the following statement from the Medical Society of New Jersey, which was referred to Division 3 of the Reference Committee on Consideration of the National Health Program:

Sept. 16, 1938.

Dr. William Carrington, President
Medical Society of New Jersey
Atlantic City, New Jersey

My dear Doctor Carrington:

I desire to suggest to you that those of us who are going to attend the special meeting of the American Medical Association as delegates from New Jersey be given an outline of what we think New Jersey has stood and does stand for.

In the first place New Jersey is most desirous that there be no recriminations about responsibility for the former attitude of organized medicine in relation to the government as regards the need of adequate medical care.

Today the federal government is planning to take care of the medical needs of many who are today unable to pay for it and the doctors in many communities should be relieved of the care of the indigent which the medical profession as a whole has so adequately and splendidly provided for in the past. New Jersey wants to aid both the government and many individual doctors who are in need of the assistance of organized medicine. To do this New Jersey believes that organized medicine must present a united front in trying to help the government to formulate a medical policy which will be of the greatest assistance to the nation and still preserve those customs which have guided ethical medical practices in the past.

New Jersey recognizes the seriousness of the problem in some localities but feels that it is much more urgent in some states than in others and more in some districts than in others of the same state. In New Jersey, by the cooperation of the local medical societies with the ERA, the problem has been largely solved. Such cooperation should be the aim of both the profession and the government for cases in actual need of medical assistance.

1. We believe in (a) subsidized medicine, not socialized medicine (b) to be applied only to the indigent poor and families of those on an income bracket below \$1,000 or \$1,500.

The principles of the suggestions offered are that the medical society of each county in every state, which contains members who alone know the medical needs and conditions of each separate district, and thus are the only ones who can properly perform the work, shall, without compensation to themselves, suggest to the federal and state governments as to how to furnish adequate medical care to all indigent and lower income bracket families that may be in need of it, and thus remove the burden from the medical profession, the burden of care of the indigent which it is now carrying almost alone, and that all the plans shall be formulated, administered and operated by organized medicine, for it is only by some such action that the development of a large political medical bureaucracy will be prevented.

With this in view New Jersey would offer the following suggestions to the House of Delegates of the American Medical Association:

A. That there shall be formed in each county a committee of the medical society of that county, whose duty shall be to formulate a medical policy as regards the indigent and families in the lower income bracket below \$1,000 or \$1,500, and to

supervise the operation of such a plan or plans in the county or district in which its members live.

B. That all bills incurred for medical services under such a plan or plans shall be presented to a committee of the county society in which the services are rendered, which shall formulate a reduced charge scheme for the county or districts of which they are members and formulate rules, and shall approve, disapprove or adjust such bills for the care of the indigent and those of the lower income brackets not in hospitals supported by municipal or state funds.

C. That those families who are in receipt of less than \$1,500 yearly income shall be furnished adequate medical care to be paid for through the municipality, county or state in which the service is to be rendered.

D. That no family with an annual income of more than \$1,500 shall be eligible to any treatment by subsidized medicine without an application to the medical society in the county in which the services are to be rendered, a committee of which shall authorize or reject applications within twenty-four hours.

E. That all medical care shall be, as far as possible, furnished by the physician of the patient's choice.

F. That in the administration, local nonprofit making and charitable organizations and groups, such as established district medical societies, clinics, hospitals and welfare agencies, shall be utilized, but that the government insist that all agencies and organizations in a community be properly coordinated before they are given the administration of funds.

A certain degree of coordination has been attempted by the Medical Society of Essex County of New Jersey with some measure of success.

A motion to have all the plans mimeographed for distribution the next day was lost for want of a second.

Message from Medical Association of Puerto Rico

The Secretary presented the following telegram from the president of the Medical Association of Puerto Rico, which was referred to the Reference Committee on Consideration of the National Health Program:

Please transmit our delegate following instructions: In alternate read before assembly. Puerto Rico chapter recognizes expansion health organization to combat transmissible and chronic disease. Accepts 50 per cent federal government aid for hospital and medical care of indigent poor. We join in move pro national health department with secretary national health in Cabinet. Puerto Rico Association rejects all forms socialization or nationalization of service as recommended in national health program.

Clipping from Washington Evening Star

The Secretary also presented a statement dealing with the investigations of the Federal Department of Justice that had appeared on Sept. 15, 1938, in the *Washington Evening Star*, which was referred to the Reference Committee on Reports of Officers and Board of Trustees.

Dr. E. H. Cary, Texas, moved that the House recess until 2:30 p. m., and that the first order of business at that time be an address by Dr. R. G. Leland, Director of the Bureau of Medical Economics of the American Medical Association. The motion was seconded and carried after discussion.

The House recessed at 1 p. m., to meet at 2:30 p. m.

Friday Afternoon, September 16

The House of Delegates reconvened at 2:40 p. m., with Dr. H. H. Shoulders, Speaker, in the chair.

Dr. R. G. Leland, Director of the Bureau of Medical Economics, addressed the House as follows:

The following is an outline of some of the main types of medical care plans now in operation or proposed throughout the United States by the medical profession and other organizations and agencies. A brief discussion of each type of approach is given and the approximate number of such efforts according to available records, which almost always understate the real number. Without prejudice to any other medical societies, I shall mention a few localities in which typical examples may be found.

1. *State and County Medical Society Plans*: One hundred and fifty-two operating, eighty proposed.—State and county

medical societies have entered into a variety of arrangements in an effort to improve the distribution of medical services. These medical society plans can be divided into three main categories:

(1) *Plans to Care for the Indigent Sick*: One hundred and eight operating, thirty-nine proposed.—Arrangements are entered into by the county medical society and local relief authorities to provide indigent sick persons with free choice of physician, usually to supplant the rather unsatisfactory and inadequate arrangement with county physicians. These arrangements follow either a per capita fee schedule or a lump sum payment basis. (See the publications "Care of the Indigent Sick," "Medical Service Plans" and "Organization of Medical Services.")

(2) *Postpayment Plans*: Twenty-seven operating, twenty-seven proposed.—These plans are organized by medical societies, often in conjunction with dentists or hospital authorities (customary title is Medical-Dental Service Bureau), to enable persons with low incomes to secure medical, dental or hospital services at rates reduced to the person's ability to pay on a deferred payment basis. (See the publications "Medical Service Plans," "Organization of Medical Services" and "Group Hospitalization," pp. 154-155.)

(3) *Prepayment Plans*: Seventeen operating, fourteen proposed.—A number of medical societies have experimented with prepayment insurance plans, which ordinarily consist of a bureau organized to obtain payments from wage earners in low income groups. Members are entitled to designated services based on a reduced fee schedule and are entitled to free choice of a physician, who is paid by the bureau on a pro rata basis according to the services he performs. These plans are in existence in Georgia, Oregon, Utah and Washington. (See the publications "Medical Service Plans" and "Organization of Medical Services.")

2. *Group Hospitalization Plans*: Seventy-eight operating, sixty-two proposed.—These plans consist of a hospital service corporation or association, usually organized by representatives of hospitals or medical societies, which contracts with member hospitals for services and, in turn, contracts with groups of persons to furnish designated hospital services on a prepayment basis. (See the publications "Group Hospitalization," "Prepayment Plans and Hospital Care" and "Group Hospitalization Contracts Are Insurance Contracts.")

3. *Hospital Insurance Companies*: Fifty-four operating.—Certain insurance companies, either newly organized companies usually on an assessment basis or already established stock or mutual companies, offer a special hospital expense only policy that provides designated cash benefits for expense due to hospital residence. There are also a great many insurance companies which offer special hospital supplements in connection with regular accident and health insurance contracts, as well as companies which offer group hospitalization on a cash indemnity basis in connection with regular group accident and health insurance. (See the report "Group Hospitalization," pp. 211-229.)

4. *Flat-Rate Plans*: Nineteen operating.—These are arrangements adopted by certain hospitals whereby an all-inclusive charge is specified for designated services; for example, \$50 for obstetrics patients exclusive of extras or the services of physician and nurse. There are variations of such arrangements called middle-rate or fixed-rate plans. (See the report "Group Hospitalization," p. 16.)

5. *Industrial Medical Care Plans*: At least 2,000.—There are two main types of organizational arrangements for medical care for employees:

(1) Most extensive are the "industrial health services," usually financed by employers, to provide first aid and emergency care for employees and to supervise plant hygiene and safety conditions.

(2) "Industrial medical service plans" provide more extensive medical care for employees and often for their dependents. "Industrial medical service plans" take a variety of forms, which can be classified as follows:

(a) Arrangements, usually financed entirely by the employer, whereby employees and sometimes their dependents receive extensive medical service from physicians employed in company-

owned hospitals or from physicians and hospitals under contract with the employer.

(b) Employee associations, financed largely by employees and in part by the employer, to provide employees and their dependents with extensive medical services in an association-owned "clinic" or hospital or by contract with an independently organized "clinic."

(c) Association of employees, financed largely by the employee and in part by the employer, to provide employees and their dependents with medical services by means of an agreed fee schedule with the local county medical society.

(d) Mutual benefit associations of employees, financed entirely by the employees, whereby funds are collected to provide benefits in cash for members. In addition to cash benefits for loss of time, several of the associations pay cash benefits for medical and hospital expenses. A recent report recorded 306 such associations. Only a few of these associations provide services "in kind" through salaried physicians and association-owned hospitals or through physicians and hospitals under contract with the association.

(e) Group insurance policies with insurance companies financed in part by the employee and in part by the employer, whereby a cash benefit equivalent to a percentage of the weekly salary is paid to an employee absent from work because of sickness or accident. Seven million employees are reported to be included under such group insurance policies. (See the publications "Group Hospitalization," pp. 9-13; "Contract Practice" and "New Forms of Medical Practice.")

6. *Medical and Hospital Benefit Organizations:* At least 500.—Such organizations include a great variety of arrangements whereby funds are accumulated from members through the sale of membership certificates or contracts. Medical and hospital services are offered through hospitals and clinics owned by the organizers or through physicians and hospitals under contract with the organizers. Some of these plans have been the most undesirable of all proposals for the distribution of medical services, such as the 143 organizations in one state which defrauded thousands of persons who thought they were purchasing low-cost medical services. Other of these organizations are wholesale buying clubs to induce physicians to provide services at a 50 per cent discount for members who pay dues. Still other such organizations are cut-rate "clinics," most of which contract with employers to provide medical services for employees. A few of these organizations are on a community-wide basis and pay cash benefits to members for designated medical services. Most of the so-called "community health associations" are privately operated organizations, contracting with a cut-rate clinic or a small group of physicians. (See the publications "New Forms of Medical Practice," "Group Hospitalization" and "Contract Practice.")

7. *Union Sick Benefit Funds and Fraternal Plans:* At least twenty-four.—These organizations are similar to mutual benefit associations except that they are not limited to one company but include all members of a trade union or a fraternal order. Most of these organizations are on a national basis and provide cash benefits for loss of time and for medical and hospital services through companies organized under the fraternal insurance laws. Frequently the local branch or lodge enters into contractual relations with local physicians and hospitals to provide medical services and hospitalization for members. Such "lodge practice" plans provide members with only a meager service and are generally considered the worst type of contract practice. (See publications "Contract Practice" and "Group Hospitalization.")

8. *Group Practice Plans:* At least 300.—Group practice or so-called "private group clinics" are arrangements whereby physicians cooperate in their practice, share office space, own certain kinds of equipment and employ lay assistance in common. Only a small percentage of such groups of physicians have entered into arrangements to provide patients with medical services on a prepayment basis. (See the publications "Group Practice Plans" and "Group Hospitalization," p. 13.)

9. *Student Health Services:* At least 300.—These are organizational arrangements in colleges and universities to supervise

and protect the health of students on campus through entrance examinations, consultations, infirmary care, instruction in personal and public hygiene and control of communicable disease. Such organization might be compared to industrial health services with particular emphasis on health education. Educators and several surveys have criticized those student health services which overemphasize curative medical services to the detriment of the more essential health education program. (See the publication "University and College Student Health Service.")

10. *Rural Medical Care Plans.*—There are two main types of rural medical care plans:

(1) "Health Associations" organized by a group of residents to guarantee a physician an annual income as an inducement to locate in the community. Subsidies and bonuses to induce a physician to locate in a rural community are also sometimes offered by local authorities or by a private individual. Only five community health associations are known to be in existence. The number of bonus or subsidy arrangements is not known.

(2) Farm Security Administration plans to provide medical service for low income or destitute farm families. In most states the arrangements enable Farm Security Administration clients to obtain a loan and to pay physicians directly on a reduced fee basis or the clients to pool their funds with a trustee who pays properly verified bills from physicians according to a reduced fee schedule. In a few states, associations of Farm Security Administration clients have been organized to hire certain physicians to provide medical service for members. Farm Security Administration plans which are usually on a county basis are in operation in twenty states. (See the publication "Rural Medical Service," pp. 72-80.)

11. *Credit and Collection Bureaus:* At least fifty operating, twenty-five proposed.—Credit and collection bureaus are organized by medical societies or by groups of physicians to provide a credit rating and collection service for members. Frequently, these bureaus arrange for postpayment of medical bills similar to medical-dental service bureaus, and some have organized plans to assist patients in financing medical bills. (See the report "Collecting Medical Fees.")

These illustrations should be sufficient to show that there has developed in the United States a large variety of methods of distributing medical services. Some of the plans have been in operation sufficiently long to reveal definite defects; others are still in a developmental and experimental stage; still others give promise of value.

The large number of plans that are now in operation do not include all the agreements between county medical societies and the Farm Security Administration. The details of these plans are on file in the Bureau of Medical Economics.

The most fortunate and hopeful feature of this development to provide means by which people may secure medical services lies in the fact that in the United States there has been and is yet the freedom to develop and direct efforts along dissimilar lines. As yet the road has not been closed by legislation to the search for a variety of appropriate ways of distributing medical services. Once that road is closed by legislation it will become increasingly difficult for county medical societies and other organizations to develop the measures that seem most appropriate for the local conditions of widely different communities.

Resolutions on Appointment of Committee to Study Data and Plans

Dr. Felix J. Underwood, Mississippi, for himself and Dr. Harvey F. Garrison, Mississippi, presented the following resolutions, which were referred to the Reference Committee on Reports of Officers and Board of Trustees:

WHEREAS, In August 1935 the President of the United States of America did name a committee, known as "The Interdepartmental Committee to Coordinate Health and Welfare Activities," and this committee did on June 14, 1938, make known at least a portion of its findings to the House of Delegates of the American Medical Association in an address by its Chairman, Miss Josephine Roche, presented by the Assistant Surgeon General of the United States Public Health Service, Dr. Warren F. Draper, and extended an invitation to the House of Delegates, or its representatives, which was accepted, to attend a meeting of the National Health Conference in Washington, D. C., July 18-20, 1938; and

WHEREAS, The findings of this committee were not entirely in accord with nor acceptable to the representatives of the House of Delegates of the American Medical Association; and

WHEREAS, The House of Delegates of the American Medical Association is not unmindful that a large percentage of our population who, because of economic conditions, are not able to pay for adequate medical care and perhaps because of this financial inability are not receiving the attention they should have; and

WHEREAS, It is the opinion of the House of Delegates that organized medicine is anxious to do all within its power to bring about a system that will offer better and more adequate medical care to the indigent and to those of the low income bracket in our country; therefore be it

Resolved, By the House of Delegates of the American Medical Association in special session in Chicago, this the sixteenth day of September 1938, that this body is in sympathy with the President of the United States in any laudable effort to improve the physical condition of such a large group of our people who are not now receiving adequate medical care; and be it further

Resolved, That the President of the United States of America is hereby respectfully requested to name a committee of five, or such a number as he may deem proper, to act with a like committee from the House of Delegates of the American Medical Association to study the data and plans accumulated by "The Interdepartmental Committee to Coordinate Health and Welfare Activities" and those available from the study of the American Medical Association, with the idea of reconciling the differences now existing as to the proper procedure to follow in order to make proper and sufficient distribution of health facilities to the "consumers of medical care" who are unable to meet such expense; and be it further

Resolved, That after the two committees have reached a conclusion as to the desired procedure that should be followed the combined committees shall submit their recommendations to the President of the United States of America, the Board of Trustees and the Speaker of the House of Delegates of the American Medical Association, the latter of whom, by order of the Board of Trustees, shall then call the House of Delegates into special session to consider such report and its final disposition.

Reference Committee on Rules and Order of Business

It was moved by Dr. H. C. Macatee, District of Columbia, seconded by Dr. S. J. Kopetzky, New York, and carried, that the Speaker appoint a Reference Committee on Rules and Order of Business. The Speaker appointed as members of the committee Drs. E. R. Cuniffe, New York, Chairman; G. Henry Mundt, Illinois, and John Z. Brown Sr., Utah.

Resolution on Continuing Conferences with Representatives of Government and Others

Dr. Andrew F. McBride, New Jersey, presented the following resolution, which was referred to the first three divisions of the Reference Committee on Consideration of the National Health Program:

WHEREAS, The House of Delegates of the American Medical Association approves of the first three broad objectives of the National Health Conference, expansion of public health service, expansion of hospital facilities, and most important of all, the medical care for the medically needy; therefore be it

Resolved, That in order to attain these objectives, representatives of the American Medical Association arrange continuing conferences with representatives of government, agriculture, labor and industry.

Resolution on Change of Medical Care for the People

Dr. Charles A. Dukes, California, in behalf of the California delegation, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The great complexity and rapid changes in social and economic conditions, and in medical science and practice, make it imperative in the best interests of the people of the United States to bring into being at an early day ways and means whereby adequate medical care may be given to all citizens, no matter to what income classes belonging; and

WHEREAS, The present organization of the American Medical Association, its constituent state medical associations, and their component county medical societies, is of a type and scope that would permit medical service of the best scientific standard and quality to be given by them in every portion of each state in the Union; and

WHEREAS, Existing ethical and procedure rules of the American Medical Association, its constituent state associations and their component county units handicap plans designed to give the aforesaid service, when the same are promoted, espoused, controlled or owned by constituent state medical associations, or by their component county medical societies, acting singly or in groups; and

WHEREAS, Recent trends and actions by political and other forces and agencies throughout the United States indicate that compulsory health insurance or similar systems that are not in accord with the ten principles adopted by the House of Delegates of the American Medical Association at the Cleveland annual session of 1934 are more than apt to be promulgated and thrust on the people and medical profession of the United States with results that would undoubtedly lead to woful deterioration in the standards and quality of medical service rendered to the people of our country; and

WHEREAS, Adoption by this House of Delegates, convened in special session in Chicago on Sept. 16, 1938, of amendments to the Principles of Medical Ethics of the American Medical Association, so worded to permit its constituent state medical associations or their component county medical societies, acting singly or in groups, to provide medical care and service, with or without hospitalization care or service, to citizen groups agreed on by the beforementioned state or county medical societies, would greatly aid in the solution of these public health and social problems; and

WHEREAS, It is of paramount importance for organized medicine at once to bring into operation principles and rules that will make it possible for state associations and their component county societies to sponsor or control or own medical care and service organizations as above outlined; and

WHEREAS, The existing Principles of Medical Ethics of the American Medical Association, as given in Chapter III, Article I, Section 4, are so worded that constituent state associations and component county medical societies cannot solicit patient groups of certain income classes for whom more adequate medical service is indicated, the ethical principles as outlined in Section 4 of Article I of Chapter III making it impossible for state and county units to engage successfully in competition with private medical service groups or organizations that have been brought into existence for profit; now therefore be it

Resolved, That we suggest that action be taken at the proper time to delete the first sixteen lines of Section 4 of Article I of Chapter III, Principles of Medical Ethics, beginning with the words "Sec. 4.—Solicitation of patients" and ending with the words "has been or is concerned" and to substitute in lieu thereof the following:

SEC. 4.—Solicitation of patients by physicians as individuals, or collectively in groups, by whatsoever name these be called, or by institutions or organizations, whether by circulars or advertisements, or by personal communications, is unprofessional; provided, however, that solicitation of patients by a constituent state association or its component county medical societies, acting singly or in groups, when said solicitation of patients is of an impersonal character and is done in the name of the aforesaid constituted units of organized medicine and for the promotion of medical service plans owned and controlled by such constituted units and designed to give more adequate medical care and service to citizens of certain stipulated income classes, shall be permissible and shall not be construed as unprofessional. This does not prohibit ethical institutions or constituted state or county medical society units from a legitimate advertisement of location, physical surroundings and special class—if any—of patients accommodated. It is also unprofessional for physicians as individuals, or collectively, or in groups, when not acting officially for state or county medical societies, singly or in groups, as before indicated, to procure patients by indirection through solicitors or agents of any kind or by indirect advertisement. It is equally unprofessional for physicians or individuals, or collectively in groups, by whatsoever name these be called, or by institutions or organizations, or by constituted units of organized medicine as above outlined, to procure patients by furnishing or inspiring newspaper or magazine comments concerning cases in which the physician or physicians have been concerned.

Statement from Medical Profession in Minnesota

Dr. W. F. Braasch, Minnesota, presented the following statement, which was referred to the Reference Committee on Consideration of the National Health Program and its Division 5:

1. The medical profession in Minnesota is in sympathy with all intelligent efforts to help indigent and low income groups to secure adequate medical care.

2. Any plan that may be adopted should leave to the medical profession and the health authorities of the individual states the exact form the plan is to take.

3. The right of the patient to freedom of choice of physician should be preserved.

4. The medical profession in Minnesota is opposed to any form of tax-supported health insurance.

Resolutions Requesting Aid in Finance or in Service

Dr. James C. Sargent, Wisconsin, presented the following resolutions, which were referred to the Reference Committee on Reports of Officers and Board of Trustees:

WHEREAS, There is promise of a movement to revolutionize the practice of medicine in America as evidenced by the interest manifested by federal and state governments in enacting legislation affecting the practice of medicine and the payment for hospital and medical services through voluntary or compulsory forms of insurance; and

WHEREAS, There appears in the report of the Proceedings of the National Health Conference, recently held in Washington, the suggestion, from high authority, that the state of Wisconsin might well be the proving ground for the radical changes in medical practice voiced before that conference; and

WHEREAS, It costs the relatively few physicians of the state of Wisconsin, or any other state society similarly threatened, a disproportionate amount to investigate claimed inadequacies in medical care prevailing therein, or to experiment with methods appearing to be suited to the correction of such inadequacies; and

WHEREAS, It seems wise, that, if such inadequacies are found to exist and if it appears proper that some new method must be devised to provide for the correction of any inadequacy so found, the development of those new methods should have the benefit of the knowledge and understanding peculiar to those engaged in the practice of medicine; therefore, be it hereby

Resolved, That the Board of Trustees of the American Medical Association be and hereby is authorized in its discretion to lend aid of the American Medical Association either in finance or in service to such studies; and be it further

Resolved, That the Board of Trustees of the American Medical Association be and hereby is authorized in its discretion to lend the aid of this Association either in finance or in service to any trial efforts at change as may be proposed by any of its constituent state units and as may in its judgment seem worthy of such aid.

Addresses of Representatives of the National Medical Association

On motion of Dr. Hilton S. Read, New Jersey, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried unanimously, a representative of the National Medical Association was invited to address the House.

ADDRESS OF DR. ROSCOE C. GILES, CHICAGO

Dr. Hilton S. Read, New Jersey, presented Dr. Roscoe C. Giles, Chicago, who addressed the House as follows:

Mr. Chairman, Members of the House of Delegates of the American Medical Association:

Unfortunately I am not now president of the National Medical Association; I am a past president of the association, but I am here with Dr. Roberts, an ex-president, and Dr. Clarence Payne of Chicago, a member of our Commission on Tuberculosis, by courtesy of the House as the representatives of the National Medical Association. Our organization is an organization which is the mouthpiece for approximately 5,000 colored physicians in America. Many of our men in the North are members of the American Medical Association. We regret that it is not possible for all of our members throughout the entire country to be members of your august body. We are very deeply interested in this subject of medical economics. At our last session, in our convention held at Hampton, Va., August 15-19 of this year, we were visited by some representatives of the federal government with certain plans which were proposed to be introduced at the coming session of Congress which if enacted would mean the initiation of state medicine in America.

It was pointed out to us that there were 40,000,000 people in America who are unable to provide adequate medical service for themselves, that of that 40,000,000 there are 6,500,000 who are members of our race in the rural districts of the South. It was furthermore pointed out to us that we had little or nothing to expect from organized medicine, that for our own self preservation it might be necessary for us to swallow wholeheartedly this plan of the federal government.

Our Executive Committee and our House of Delegates considered the matter very seriously and we arrived at the very definite conclusion that there are no insurmountable fundamental difficulties in the field either of medical economics or of professional relationships between the majority and minority groups which cannot be amicably settled within the ranks of organized medicine. Therefore, in accepting the suggestions that were made to us that we might consult certain departments of the federal government whose forces are now arrayed against organized medicine, we chose to walk in and present ourselves a few days ago before your distinguished body in session and to there make certain requests and to make certain definite statements, some of which I shall here and now repeat.

The plight of the colored physician in America has been very pitiful. I will not take the time to rehearse all of those things. You men who are teachers in our universities throughout the country know these as well as we do. The thing that has impressed us greatly recently has been the fact that under the Emergency Relief Act so far colored physicians throughout the United States as a whole have not been permitted to take care of colored patients, thus violating a fundamental principle of your great organization, the free choice of physician by patient.

By that same token we have also been prohibited from sharing, as we should like to share, in the provisions for the control of venereal disease throughout this country. We believe that those are problems which can be and will be worked out and we hope will be worked out during your deliberations here.

We are vitally interested, as you are, in all these public health problems. We would like, if permitted, to work hand in hand with you on these matters. It is safe to say, as we said last night, that as no man in America is safe unless the humblest citizen is safe, so is it equally true that no physician in America is safe so far as social security is concerned until the humblest physician has been protected.

We therefore appear before your organization with the request that, if you can see your way clear to do so, you again enunciate the doctrine you have already done of the free choice of the physician by the patient, and, furthermore, to be more specific, that the Negro physicians be permitted anywhere in America to take care of Negro patients if those patients so desire.

We would like to further emphasize that, acting along those principles which were adopted by us in convention, we have decided to go along with you in every way humanly possible, because we know the situation. We have had an opportunity to see socialized medicine in Europe. Dr. Roberts, a distinguished member of this committee, studied it in England, Dr. Payne studied it in France and I have had an opportunity to study it in Vienna for seventeen and a half months, and I am very sure that none of us would like to see the conditions that obtain in Europe at the present time, and which obtained there at the time I was a student in the University of Vienna.

Men who are specialists in that particular city got 50 cents per patient, and the average physician worked for about 10 groschens, or about 7 cents a patient. It was a rare thing for them ever to eat meat; they could not afford to buy it.

If we have socialized medicine in America, I am very sure, as you must be sure, that the standards of medical practice will degenerate, that the pay of physicians will not be adequate for them to keep up with their educational facilities and post-graduate study and the patients again will suffer as they have suffered in Europe.

Therefore, in conclusion may I say that we lend to you our support and our sympathies in the struggle that you have against the forces arrayed against you and promise you that so far as humanly possible we will give you our undivided strength.

ADDRESS OF DR. CARL G. ROBERTS, CHICAGO

It was moved by Dr. W. F. Braasch, Minnesota, that the House extend the same privileges of the floor to the other representatives of the National Medical Association present if they so wished. The motion was seconded by Dr. Walter R. Steiner, Connecticut, and carried unanimously.

Mr. Speaker and Officers and Members of the House of Delegates:

As an additional member of the committee representing the National Medical Association, I wish to supplement and to further emphasize the remarks that have been made by our chairman, Dr. Giles. We want to bring to you the good will of the National Medical Association and to assure you that this is a momentous event when we show to the outside world through our reception here by your gracious and distinguished body that whatever difference in point of view may exist internally in the ranks of medicine, to those forces that are arrayed against us that are seeking to disintegrate organized medicine we present a united front of opposition, that there are no problems, as has just been said, which are so insurmountable or so difficult that they cannot be solved amicably within the ranks of organized medicine.

As I heard Dr. Snyder present his plan here this morning, I wondered if he was thinking, as I was thinking, in amazement at the plan that was presented at the Planning Committee of the Republican Party held recently in Chicago, where we were present not as partisan politicians but as invited guests to represent our several and component societies; we heard

presented there a deal that surpassed the New Deal, a proposal to socialize medicine completely from top to bottom. I wonder whether those of you who were present listened with the same amazement with which the members of the National Medical Association listened. I assure you that we know definitely, as we told them on that particular occasion, that we know what we want concretely and what we don't want, and one thing that we do not want is any socialization of medicine, and I want to assure you gentlemen in whose hands the fate and destiny of the American Medical Association lies, that we are quite willing to subscribe to whatever you decide upon on this occasion, that we believe, as you do, that the fate of medicine in America, that the fate of the health problem so far as it affects the laity, is best put into the hands of those who are trained especially to take care of them, in other words in the hands of the American doctor and the American dentist, and we believe with confidence in your sense of fair play and in your sense of justice and in your ability and your wisdom to see to it that those handicaps which have been mentioned to you, under which we labor, will be adjusted and removed, because we feel that you will agree with us that the health of one tenth of this population, who are Negroes, in the final analysis must lie largely in the hands of the Negro doctor, and as long as that minority which has the highest rates of morbidity and mortality in these preventable diseases is a drag on the health situation of America, so long must we be prepared to meet it.

Again, in conclusion, we want to thank you on behalf of our association, which appreciates more than you can know this gesture of good will. I have just received this afternoon a letter from our president in which he has answered a copy of an attack that appeared as an editorial in a newspaper last week on both the American Medical Association and the National Medical Association, and that letter of his will be published in that paper this week, an answer to those forces that are inviting us to put our fate in the hands of propagandists who use a system so often used when they want to divide a house against itself, by laying the matter in the hands of outsiders. We propose to rely on the members of this Association. There is no section and no division line in friendship or medical principles regardless of race involved, and we propose to march forward with you in all that is best for American medicine if you will permit us to do so.

ADDRESS OF DR. CLARENCE H. PAYNE, CHICAGO

Mr. Chairman and Members of the House of Delegates:

The previous speakers have laid before you most of the things that have been close to our hearts, but I may add this: that it was the consensus of opinion of the men from Texas and the men from all sections of this country that you stimulate and advance the health and the protection of the Negro patient in the Southland as well as in the Northland by affording us the courtesy and the dignity of respect that you have today. We wish to add that in their involvement of this question they felt that it brought itself down in medical economics to the recognition of the patient and physician, that if we considered all our problems from this angle most of them would be solved, because wherever we have a separation of that ideal we have always had failure. We have felt that we needed to inform the government that we regarded Americans as divided, for practical purposes, into three classes: one class able to pay for any amount of hospital and medical care, and they certainly should not be interfered with by anybody; the middle group of course needing some supplementary aid, probably, but that aid has always been able to be worked out by American initiative, and we felt that the hospitalization plan as worked out here in Chicago, if it were made more comprehensive, could extend to all employed persons in the United States, operating by private enterprise and supervised by medical boards so that any mistakes in its operation could be corrected, and that would afford them a solution and help them to meet their problems; in regard to the indigent we felt that here too the patient and physician relationship should exist, and that there should of course, if necessary, be federal subsidy but that in the subsidy of these patients it should be also supervised by medical commissions, whether they be state or whether they be under the

head of your American Medical Association. In that way, rather than being exploited, the patients and the physicians of this country would reach an amicable settlement of all their difficulties.

Those are the general principles on which we felt that our case would rest and that we would wait on you for guidance in the working out of those details which are necessary to arrive at a proper solution.

I thank you for this privilege.

Action of Medical Society of Virginia

Dr. Walter B. Martin, Virginia, presented the following statement, reading the amendment therein more as his own personal view, all of which was referred to the five divisions of the Reference Committee on Consideration of the National Health Program:

A special meeting of the Council of the Medical Society of Virginia was held on September 8 to confer with its delegates to the American Medical Association with regard to the proposed program of the National Health Conference, the subject for discussion at a special meeting of the House of Delegates of the American Medical Association in Chicago, on September 16.

The following resolution, with amendment, was adopted:

1. The cost of medical care to the indigent is an obligation of the entire citizenry and should be met by equitable public taxation.
2. The low income group needs and should have assistance in meeting the costs of medical care.
3. Any program for the extension of medical facilities should be directed by the medical profession as the group best qualified by experience and training; and, therefore, the Council of the Medical Society of Virginia requests the House of Delegates of the American Medical Association to cooperate with all agencies, private or governmental, local or federal, in every effort to make available complete medical facilities to all citizens regardless of economic status, provided the control and direction of such efforts be kept in the hands of the medical profession as the only group qualified by experience and training to direct such activities.

Amended to include the following: "with due consideration and in accordance with resolutions presented by the Medical Economics Committee of the Medical Society of Virginia."

While your committee is fully conscious of the desirability of extending medical care to all those that are in need of such care, we are persuaded that the preservation of medical freedom is of more importance to the present and future welfare of our people than any other consideration.

We are opposed to the recommendation of the National Health Conference for the following reasons:

1. That no grave national emergency exists from the standpoint of need for medical service. The statement that one third of our population is without proper medical care is contrary to common knowledge and cannot be supported by actual figures based on any adequate survey.
2. That we deny the health of the individual is a concern of government except so far as that individual's state of health menaces the general welfare. Provision should be made for the medical care of the indigent sick by local governments, supplemented in certain poor communities by state or federal aid.
3. That government is properly concerned with public health measures that have to do with the prevention of communicable diseases, with sanitation, industrial hazards and such like conditions that have effect on the general welfare. Most of these measures can best be directed by local government units, certain ones by the individual states, and a few by the federal government. In certain instances international cooperation is required. It is our firm conviction that the line of demarcation between the functions of these several political units should be preserved and that the concentration of preventive health work in Washington would be disastrous in its consequences.
4. That we are satisfied the creation of a huge fund to be controlled and expended by an agency of the federal government for medical education, endowment of research institutions, preventive medicine, medical relief work and the subsidizing of practitioners would destroy medical independence and, eventually, medical progress. In an undertaking so vast, political influence would soon become paramount. This influence would make itself felt not only in those departments concerned

in the distribution of medical service but in public health projects, teaching institutions and research laboratories. We do not believe that there is any individual or any agency capable of administering so large a trust or with ability sufficiently great to enable him or it to see and understand the various factors that enter into the problem of disease prevention and medical care throughout the entire country.

Report of Reference Committee on Rules and Order of Business

Dr. Edward R. Cuniffe, Chairman, presented the following report, and the procedure therein recommended was adopted on motion of Dr. Cuniffe, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried:

Your Reference Committee on Rules and Order of Business recommends that the introduction of new business at this session be limited to 11 o'clock tomorrow morning unless by unanimous consent of the House, and that the first order of business in the morning be the receiving of the reports of reference committees, to be followed by the introduction of new business up to 11 a. m., unless by unanimous consent of the House.

Representatives of American Dental Association

On motion of Dr. E. L. Henderson, Kentucky, seconded by Dr. A. T. McCormack, Kentucky, and carried unanimously, the representatives of the American Dental Association were invited to address the House, but Dr. H. B. Pinney, secretary of that organization, stated that they had nothing to offer.

On motion, duly seconded and carried, the House adjourned at 3:50 p. m., to meet Saturday, September 17, 1938, at 9:30 a. m.

Second Meeting—Saturday Morning, September 17

The House of Delegates was called to order at 9:50 a. m., Saturday, September 17, by the Speaker, Dr. H. H. Shoulders.

Report of Reference Committee on Miscellaneous Business

Dr. W. H. Seemann, Chairman, presented the following report:

1. A Plan for Publicity Against Regimentation of Physicians: This communication is a very clear and informative statement of a plan devised and carried out in seven counties in West Virginia, a plan well worth studying by our component societies. Especially noteworthy is the emphasis placed on the importance of each and every physician constantly and persistently carrying on a campaign of education among his individual patients. There is no definite resolution proposed in this communication. The committee again commends the work of the Parkersburg Academy of Medicine to the consideration of our members but recommends no other action by the House at this time.

2. Resolution on Change of Medical Care for the People: This resolution embodies a proposed change in the wording of Section 4 of Article I of Chapter III of the Principles of Medical Ethics of the American Medical Association so that it will read as follows:

SEC. 4.—Solicitation of patients by physicians as individuals, or collectively in groups, by whatsoever name these be called, or by institutions or organizations, whether by circulars or advertisements, or by personal communication, is unprofessional; provided, however, that solicitation of patients by a constituent state association or its component medical societies, acting singly or in groups, when said solicitation of patients is of an impersonal character and is done in the name of the aforesaid constituted unit of organized medicine and for the promotion of medical service plans controlled by such constituted units and designed to give more adequate medical care and service to citizens of certain stipulated income classes, and when such plan or plans shall have been approved by the proper constituent state association, shall be permissible and shall not be construed as unprofessional.

The proponents of this resolution have convinced the reference committee that an emergency exists and that any undue delay in the adoption of this resolution might be prejudicial to the best interests of the public and organized medicine.

Your reference committee, finding no established rule contrary to such action, recommends the adoption of this resolution.

3. Resolutions on Public Announcement of Plans Recommended by House of Delegates: These resolutions embody a request that the American Medical Association immediately

engage in an elaborate publicity campaign to be financed by the said Association from its own funds with aid of voluntary contributions.

It developed in the discussion on these resolutions that the publicity now enjoyed by the American Medical Association is far greater than imagined by the average member; that embarking on such an enterprise as suggested at this time might be hazardous and certainly gives no promise of returns commensurate with the costs, and that the treasury of the American Medical Association could hardly stand the strain of such costs.

Your committee recognizes the brave and loyal sentiments which actuated the proponents but believes that the best disposition of the resolutions is to refer them to the Board of Trustees for such action and disposition as it may find feasible.

Respectfully submitted.

W. H. SEEMANN, Chairman.
CHARLES B. REED.
MCLAIN ROGERS.
H. G. HAMER.
FELIX J. UNDERWOOD.

The first and third sections of the report of the reference committee were adopted on motions of Dr. Seemann, duly seconded and carried.

The second section of the report was referred to the Judicial Council on motion of Dr. A. T. McCormack, Kentucky, seconded by Dr. Samuel J. Kopetzky, New York, and carried after discussion.

The report of the reference committee was adopted as a whole, with the exception of the second section, which had been referred to the Judicial Council, on motion of Dr. Seemann, seconded by Dr. A. T. McCormack, Kentucky, and carried.

Report of Reference Committee on Credentials

Dr. Deering G. Smith, Chairman, presented the following report, which was adopted on motion of Dr. Smith, seconded by Dr. William H. Myers, Georgia, and carried:

The Reference Committee on Credentials reports that, out of a possible registration of 174 delegates, 165 have been registered at this special session.

Roll Call

It was moved by Dr. A. T. McCormack, Kentucky, seconded by Dr. S. J. Kopetzky, New York, and carried, that the House dispense with the roll call.

On motion of Dr. Samuel J. Kopetzky, New York, seconded and carried, the House recessed for thirty minutes to give reference committees time to prepare their reports.

Report of Reference Committee on Reports of Officers and Board of Trustees

Dr. Terry M. Townsend, Chairman, presented the report, which is herewith submitted as amended:

1. *The Address of the Speaker:* After narrating the difficulties which have beset the profession during the last few years, the Speaker points out the responsibilities of this House of Delegates. Your committee commends him for accentuating the importance of the House of Delegates as a forum to which every medical problem may be presented with the assurance of its calm consideration and wise disposition. He reiterates the fundamental importance of the ten principles or commandments already established in the consideration of any question involving the distribution of medical care.

2. *The Address of the President:* Seldom is it the privilege of our deliberative assemblies to have presented to them so clear and convincing an exposition of principles related to the subjects under discussion and couched in such scholarly diction.

The President's defense of the traditional ethics of the profession serves again to emphasize how basic they are in the maintenance of our professional standards, and his concern that all plans be measured in terms of results in morbidity and mortality indicates the principal criterion which should be applied.

He points to the indefiniteness of the National Health Program and the absence of opportunity for the presentation of alternative proposals or the detailed discussion of any part of the plan, the one agreement being the need for a Cabinet office of health and medical service. Your committee commends his clear definition of the relation between the physician and

the indigent and between the physician and the mutual benefit institution and the maintenance of the right of the physician to determine the conditions of his service. Above all your committee firmly supports his refutation of the radical speakers' charges that we oppose changes from the desire for more and more money, which he characterized as "an outrageous misstatement of our attitude."

He forcibly presents the fundamental tenet, applicable to the problems now before this body, opposing: (1) the disposal of professional services under conditions preventing adequate service, and the disposal of professional services to the financial profit of lay bodies, as being against sound public policy; (2) all meddling in medical economics consisting of vague plans for the indigent and quasi-indigent; (3) making the distribution of medical services a political football. He favors: (1) plans now carried on under the auspices of component medical societies, provided these plans are in accord with the principles and policies adopted by the American Medical Association, with a view of securing wider distribution of medical service; (2) group hospital insurance with proper safeguards to the physician and the patient; (3) suitable care for the indigent by municipal, county, state and federal institutions; (4) the principle of insurance when nonpolitically managed and when the funds are not dissipated among employees of the organization not directly concerned with rendering the service.

3. After commenting on the mutual confidence and respect engendered in the physician-patient relation, the President discusses the unfair picture painted by speakers at the National Health Conference. They depicted us as a nation one third ill fed, housed and cared for in health, dying in numbers for lack of our services. Factual knowledge to check on such statements is now in process of accumulation. Physicians everywhere are urged to return promptly the questionnaire prepared by the American Medical Association. Only by the evidence so obtained can your officers be in a position to establish the actual facts. Finally, the President again calls attention to the fact that the long established principles and policies of the American Medical Association do not preclude expansion of medical care to the mass of the underprivileged when their status is so established.

4. *The Address of the President-Elect:* Our President-Elect in his brief but sententious address uses no uncertain terms in dealing with recent widespread unfair criticism of the medical profession. He is to be recommended for the straightforward manner in which he attacks the hostile program apparently emanating from unfriendly sources. He details a few of the numerous sacrifices which are continually being made by the medical profession without thought for recompense and which are apparently overlooked by carping critics.

Not only does he call attention to economic insufficiency as a common cause of ill health but he refutes a favorite argument that widespread unemployment is based on lack of medical needs. He calls attention to the fact that the medical profession is voluntarily responsible for the social elements of the healing arts. He cites our medical publications as examples of the devotion to scientific medicine and devoid of selfish interest. In fact, he states that "never at any time, in any way, have our activities been motivated by selfish purposes." On the eve of this epoch-making session of the House of Delegates he points out that the one interest of this body is whether the proposals will contribute to the prevention of disease, prolongation of life and the alleviation of suffering, and he urges us to oppose doctrines which would eventually lower the standards of medical service. He emphasizes the fact that no one plan can meet the needs of every section of the country and makes it plain that no plan can be successful without the wholehearted cooperation of the medical profession. He ends with the warning that it is our plain duty to see that the structure of American medicine is not wrecked.

5. *Report of the Board of Trustees:* Attention is directed to the fact that this is the third time in history that the House of Delegates has been called to a special session. The report described the circumstances under which the National Health Conference at Washington in July was held. It was intimated that the proposals resulting from this conference will be the

basis for presenting legislation to the next Congress importantly affecting medical practice. The chairman of the Board calls attention to the responsibility placed on the members of this House of Delegates since we must formulate a policy for immediate needs as well as future exigencies.

Your reference committee highly commends the Board of Trustees for its willingness to submit to investigation by any authorized agency on the nature of its organization, work, conduct and activity. Firm in a belief in the probity of our officers, and confident of their adherence to established federal law, your reference committee recommends that, in the event of an indictment, this House of Delegates give full support to the Board of Trustees in defending such litigation to the utmost, with every means in its power, exhausting, if necessary, the last recourse of distinguished legal talent, to establish the ultimate right of organized medicine to use its disciplines to oppose types of contract practice damaging to the health of the public.

6. Your committee has studied with interest the action of the Board of Trustees in the matter of the Social Security Act and heartily commends the action of the Board. It recommends that this House of Delegates assure the Trustees of their full support in all efforts to establish the position of the American Medical Association as a scientific and educational organization.

7. *Resolutions Requesting Aid in Finance or in Service:* Your reference committee views with sympathy this request and listens with interest to its proponents. It is of the opinion that it is unwise to suggest any change of policy in this regard to the Board of Trustees and recommends that the request be referred to the Board of Trustees for its consideration.

8. *Resolutions on Appointment of Committee to Study Data and Plans:* These resolutions presented by the delegates from the state of Mississippi relative to the appointment of a joint committee by the President of the United States and the President of the American Medical Association in cooperation with the Board of Trustees meets with the full approval of your reference committee.

Respectfully submitted.

TERRY M. TOWNSEND, Chairman.
WILLIAM F. BRAASCH.
E. L. HENDERSON.
S. P. MENGEL.
CHARLES W. ROBERTS.

The first and second sections of the report of the reference committee were adopted as amended, on motion of Dr. Townsend, duly seconded and carried after discussion.

Sections 3 to 7, inclusive, of the report of the reference committee were adopted on motions of Dr. Townsend, duly seconded and carried.

The eighth section of the report of the reference committee was laid on the table for the time being, on motion of Dr. S. J. Kopetzky, New York, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried.

The report of the reference committee was adopted as a whole, with the exception of the eighth section, which had been laid on the table, on motion of Dr. Townsend, seconded by Dr. John Z. Brown Sr., Utah, and carried.

Communication from the National Medical Association

Dr. Hilton S. Read, New Jersey, requested unanimous consent from the House for the presentation of the following communication from the National Medical Association, which was granted:

Chicago, Illinois,
September 16, 1938

We, the accredited delegates from the National Medical Association, wish to express our deep appreciation of the gracious courtesies of the officers and delegates of the American Medical Association.

As a matter of record, and in order to present a completely unified front of organized medicine against any encroachment on its prerogatives, we submit the following proposals:

1. That all classes of American citizens have a free choice of their physician.

2. That organized medicine rededicate itself to the maintenance of the physician-patient relationship.

3. (a) That the lower income groups be assisted in bearing the heavy cost of hospitalization by means of a nonprofit hospitalization plan, preferably under private control, endorsed and supervised by properly delegated bodies of organized medicine.

(b) That this plan be comprehensive enough to permit any and all regularly employed citizens of this income class to obtain its benefits.

4. (a) That the cost of medical and hospital care of the indigent be subsidized by the city, state or federal governments, singly or conjointly.

(b) That the operation of such indigent care shall be at all times subjected to the closest scrutiny by the properly delegated representatives of organized medicine.

(c) That wherever such medical or hospital care is operative, and organized medicine, through its national or local organizations collaborates in furnishing such medical or hospital care, ample and proportionate provision shall be made for the participation in such medical and hospital care by all members of organized medicine, without regard to race or creed.

5. That in those states or localities where there is not now provided opportunities for Negro physicians to become members of branches of the American Medical Association, the local branches of the National Medical Association be recognized for such physicians as a component part of organized medicine and shall thereby receive the opportunity of engaging in all activities, responsibilities and emoluments accruing therefrom, having thereby the freedom to practice on the members of their own group.

6. That in order to promote a better understanding and cooperation among the physicians of America there be appointed properly delegated committees, annually, to act as liaison and coordinating bodies from the American Medical Association and the National Medical Association.

7. That the American Medical Association take cognizance of the need of the colored citizens for increased hospital facilities, particularly tuberculosis hospitals.

8. That the American Medical Association feel welcome and free at any and all times to assist and suggest improvement in the standards of medical and hospital practice of the constituent and national bodies of the National Medical Association, and shall provide opportunities of expression for any just grievances that may arise from the National Medical Association.

Respectfully submitted.

ROSCOE C. GILES, M.D., Chairman.
CARL G. ROBERTS, M.D.
CLARENCE H. PAYNE, M.D.

This communication was referred to the Reference Committee on Consideration of the National Health Program.

Statement from Reference Committee on Consideration of the National Health Program

Dr. Walter F. Donaldson, Chairman, stated that the chairmen of the five divisions of the Reference Committee on Consideration of the National Health Program were at work on the general recommendations submitted by each division and that the reference committee suggested that in the meantime a member of each division read to the House of Delegates for information and discussion but not for action the report of the respective division of which he is a member.

These reports were read by: Drs. A. A. Walker, Alabama, for Division 1; Holman Taylor, Texas, for Division 2; E. H. Skinner, Section on Radiology, for Division 3; John H. Fitzgibbon, Oregon, for Division 4, and Henry C. Macatee, District of Columbia, for Division 5.

The House recessed at 12:45 p. m., to meet at 2 p. m., on motion of Dr. A. T. McCormack, Kentucky, seconded by Dr. J. E. Paullin, Section on Practice of Medicine, and carried.

Saturday Afternoon, September 17

The House reconvened at 2:10 p. m., Saturday, September 17, with Dr. H. H. Shoulders, Speaker, presiding.

Report of Judicial Council

Dr. George Edward Follansbee, Chairman, presented the following report, which was adopted on motion, duly seconded and carried:

This is a special meeting of the House of Delegates called on the recommendation of the Board of Trustees to consider matters pertaining to the recent National Health Conference and such others as may be referred to it by the Board of Trustees.

The subject of the amendment of the Principles of Medical Ethics is not included in the matters for which this special session was called nor has it been referred to this House by the Board of Trustees, for which reason the Judicial Council recommends that no action be taken on the resolution introduced by Dr. Charles A. Dukes in behalf of the California delegation.

General Discussion

Dr. H. H. Shoulders, Speaker, declared the next order of business to be the discussion of the tentative reports of the subcommittees, which had been presented to the House previously for information and discussion but not for action.

DEFINITION OF THE TERM "MEDICALLY INDIGENT"

During the discussion, Dr. Michael A. Tighe, Massachusetts, moved that Division 2 of the Reference Committee on Consideration of the National Health Program be requested to define the term "Medically Needy" or "Medically Indigent." The motion was seconded by Dr. Charles B. Reed, Illinois. The Chairman ruled that since the motion was in the nature of a request to the reference committee for certain action by the committee if it saw fit to act, it was in order. The Speaker called for a standing vote and declared that the motion was adopted, there being 60 votes in favor of it and 56 opposed to it.

There was further discussion of the tentative reports, a short recess and then Dr. H. A. Luce, Chairman of Division 2 of the Reference Committee on Consideration of the National Health Program, presented a definition of the term "Medically Indigent" and moved its adoption. As amended, it reads:

A person is medically indigent when he is unable, in the place in which he resides, through his own resources, to provide himself and his dependents with proper medical, dental, nursing, hospital, pharmaceutical and therapeutic appliance care without depriving himself or his dependents of necessary food, clothing, shelter and similar necessities of life, as determined by the local authority charged with the duty of dispensing relief for the medically indigent.

The motion was seconded by Dr. Horace J. Brown, Nevada, and the Speaker ruled that the adoption of the definition was out of order unless the definition was incorporated into the report of the committee. During the discussion, Dr. E. H. Skinner, Section on Radiology, requested the section report of Dr. H. A. Luce, Chairman of Division 2, and was informed by Dr. Olin West, Secretary, that the reports of the various divisions had not been filed with the Secretary but were in the hands of the Reference Committee on Consideration of the National Health Program.

Presentation of Dr. G. Harvey Agnew

Dr. Olin West, Secretary, announced that Dr. G. Harvey Agnew, Associate Secretary of the Canadian Medical Association, was in the audience, and Dr. H. H. Shoulders, Speaker, requested Dr. Agnew to come to the platform, to be presented to the House.

Report of Reference Committee on Consideration of the National Health Program

Dr. Walter F. Donaldson, Chairman, presented the report of the reference committee, which, as amended, reads as follows:

Since it is evident that the physicians of this nation, as represented by the members of this House of Delegates convened in

special session, favor definite and decisive action now, your committee submits the following for your approval:

1. Under Recommendation I on Expansion of Public Health Services: (1) Your committee recommends the establishment of a federal department of health with a secretary who shall be a doctor of medicine and a member of the President's Cabinet. (2) The general principles outlined by the Technical Committee for the expansion of Public Health and Maternal and Child Health Services are approved and the American Medical Association definitely seeks to cooperate in developing efficient and economical ways and means of putting into effect this recommendation. (3) Any expenditures made for the expansion of public health and maternal and child health services should not include the treatment of disease except so far as this cannot be successfully accomplished through the private practitioner.

2. Under Recommendation II on Expansion of Hospital Facilities: Your committee favors the expansion of general hospital facilities where need exists. The hospital situation would indicate that there is at present greater need for the use of existing hospital facilities than for additional hospitals.

Your committee heartily recommends the approval of the recommendation of the technical committee stressing the use of existing hospital facilities. The stability and efficiency of many existing church and voluntary hospitals could be assured by the payment to them of the costs of the necessary hospitalization of the medically indigent.

3. Under Recommendation III on Medical Care for the Medically Needy: Your committee advocates recognition of the principle that the complete medical care of the indigent is a responsibility of the community, medical and allied professions and that such care should be organized by local governmental units and supported by tax funds.

Since the indigent now constitute a large group in the population, your committee recognizes that the necessity for state aid for medical care may arise in poorer communities and the federal government may need to provide funds when the state is unable to meet these emergencies.

Reports of the Bureau of the Census, of the U. S. Public Health Service and of life insurance companies show that great progress has been made in the United States in the reduction of morbidity and mortality among all classes of people. This reflects the good quality of medical care now provided. Your committee wishes to see continued and improved the methods and practices which have brought us to this present high plane.

Your committee wishes to see established well coordinated programs in the various states in the nation, for improvement of food, housing and the other environmental conditions which have the greatest influence on the health of our citizens. Your committee wishes also to see established a definite and far reaching public health program for the education and information of all the people in order that they may take advantage of the present medical service available in this country.

In the face of the vanishing support of philanthropy, the medical profession as a whole will welcome the appropriation of funds to provide medical care for the medically needy, provided, first, that the public welfare administrative procedures are simplified and coordinated; and, second, that the provision of medical services is arranged by responsible local public officials in cooperation with the local medical profession and its allied groups.

Your committee feels that in each state a system should be developed to meet the recommendation of the National Health Conference in conformity with its suggestion that "The role of the federal government should be principally that of giving financial and technical aid to the states in their development of sound programs through procedures largely of their own choice."

4. Under Recommendation IV on a General Program of Medical Care: Your committee approves the principle of hospital service insurance which is being widely adopted throughout the country. It is susceptible of great expansion along sound lines, and your committee particularly recommends it as a community project. Experience in the operation of hospital service insurance or group hospitalization plans has demonstrated that these plans should confine themselves to provision of hospital facilities and should not include any type of medical care.

Your committee recognizes that health needs and means to supply such needs vary throughout the United States. Studies indicate that health needs are not identical in different localities but that they usually depend on local conditions and therefore are primarily local problems. Your committee therefore encourages county or district medical societies, with the approval of the state medical society of which each is a component part, to develop appropriate means to meet their local requirements.

In addition to insurance for hospitalization your committee believes it is practicable to develop cash indemnity insurance plans to cover, in whole or in part, the costs of emergency or prolonged illness. Agencies set up to provide such insurance should comply with state statutes and regulations to insure their soundness and financial responsibility and have the approval of the county and state medical societies under which they operate.

Your committee is not willing to foster any system of compulsory health insurance. Your committee is convinced that it is a complicated, bureaucratic system which has no place in a democratic state. It would undoubtedly set up a far reaching tax system with great increase in the cost of government. That it would lend itself to political control and manipulation there is no doubt.

Your committee recognizes the soundness of the principles of workmen's compensation laws and recommends the expansion of such legislation to provide for meeting the costs of illness sustained as a result of employment in industry.

Your committee repeats its conviction that voluntary indemnity insurance may assist many income groups to finance their sickness costs without subsidy. Further development of group hospitalization and establishment of insurance plans on the indemnity principle to cover the cost of illness will assist in solution of these problems.

5. Under Recommendation V on Insurance Against Loss of Wages During Sickness: In essence, the recommendation deals with compensation of loss of wages during sickness. Your committee unreservedly endorses this principle, as it has distinct influence toward recovery and tends to reduce permanent disability. It is, however, in the interest of good medical care that the attending physician be relieved of the duty of certification of illness and of recovery, which function should be performed by a qualified medical employee of the disbursing agency.

6. To facilitate the accomplishment of these objectives, your committee recommends that a committee of not more than seven physicians representative of the practicing profession, under the chairmanship of Dr. Irvin Abell, President of the American Medical Association, be appointed by the Speaker to confer and consult with the proper federal representatives relative to the proposed National Health Program.

Respectfully submitted.

WALTER F. DONALDSON, Chairman.
WALTER E. VEST.
H. A. LUCE.
FRED W. RANKIN.
FREDERIC E. SONDERN.

It was moved by Dr. Donaldson, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried after discussion, that the first section of the report of the reference committee, dealing with Recommendation I on Expansion of Public Health Services, be adopted.

The second section of the report of the reference committee, referring to Recommendation II on Expansion of Hospital Facilities, was adopted as amended, on motion of Dr. Donaldson, seconded and carried after discussion.

Dr. Donaldson moved that the third section of the report, with reference to Recommendation III on Medical Care for the Medically Needy, be adopted. The motion was seconded by Dr. A. T. McCormack, Kentucky, and carried.

Dr. Donaldson read the fourth section of the report of the reference committee, dealing with Recommendation IV on a General Program of Medical Care, and moved its adoption. The motion was seconded by Dr. S. J. Kopetzky, New York. Many recommendations were offered by the delegates, after which Dr. Donaldson suggested that Dr. Fred W. Rankin, Chairman, and other members of Division 4 of the reference committee, together with those who offered the recommendations, retire for a few minutes to amend this part of the report.

On motion of Dr. Donaldson, seconded by Dr. S. J. Kopetzky, New York, and carried, the fifth section of the report, referring to Recommendation V on Insurance Against Loss of Wages During Sickness, was adopted.

The sixth section of the report of the reference committee, recommending the appointment of a committee under the chairmanship of Dr. Irvin Abell, President of the American Medical Association, was adopted on motion of Dr. Donaldson, seconded by several and carried after discussion.

After a short recess, Dr. Fred W. Rankin, Chairman of Division 4 of the reference committee, brought in an amended report, which after discussion and amendment was adopted on motion of Dr. Rankin, seconded by several and carried.

The report of the reference committee as a whole was adopted as amended, on motion of Dr. Donaldson, seconded by Dr. A. T. McCormack, Kentucky, and carried by a rising vote.

Committee to Confer and Consult with Proper Federal Representatives

Dr. H. H. Shoulders, Speaker, appointed the members of the Committee to Confer and Consult with Proper Federal Representatives, as follows:

Drs. Irvin Abell, President of the American Medical Association, Chairman; Walter F. Donaldson, Pennsylvania; Walter E. Vest, West Virginia; H. A. Luce, Michigan; Fred W. Rankin, Section on Surgery, General and Abdominal; Frederic E. Sondern, New York; E. H. Cary, Texas. Drs. Rock Sleyster, President-Elect, and Olin West, Secretary, were declared by the Speaker to be members of this committee, ex officio.

Address of Dr. Malcolm T. MacEachern

Dr. H. H. Shoulders, Speaker, presented Dr. Malcolm T. MacEachern, Associate Director of the American College of Surgeons, who addressed the House as follows:

Mr. Speaker and Members of the House of Delegates:

I do not want to take up your time, but I was rather pleased with the wording of the report as submitted, and I saw in it a good deal of solution to some of the problems without amplifying it or going into more detail than you have so stated. I said to my side partner there that I wouldn't try to explain these things much more because you have there the fine principles which can be worked out and I think can be worked out with utmost safety as far as I could interpret the report as it was read.

I believe the group hospitalization plans as they are set up and controlled by the medical societies and the hospital people under proper boards should be a very safe procedure and I think the extension will go on safely, and what you have said in addition to that struck me, on thinking it over as rapidly as I could, as a very good principle that you are advocating at present.

I would not try to look at some problems that might arise which will have to be settled by your organization as it is perfected.

Resolution on Expansion of Bureau of Medical Economics

Dr. E. H. Skinner, Section on Radiology, presented the following resolution, signed by several members of the five divisions of the Reference Committee on Consideration of the National Health Program, which was adopted on motion of Dr. Skinner, seconded by Dr. H. B. Everett, Tennessee, and carried:

WHEREAS, There is a demand among state and county medical associations for help and advice, for surveys and the development of local and state programs for the care of the indigent and low income groups of the people; therefore be it

Resolved, That it is the sentiment of this House of Delegates that it would heartily approve of an action by the Board of Trustees looking toward the sensible expansion of the Bureau of Medical Economics to accommodate the immediate and growing demand.

Expressions of Appreciation

Expressions of appreciation were extended to the Reference Committee on Consideration of the National Health Program, to each of its five divisions, to the staff of the American Medical Association and to the Speaker.

The resolutions from the Mississippi delegates, which had been laid on the table, were not taken up, because Dr. H. F. Garrison, Mississippi, stated that the report of the Reference Committee on Consideration of the National Health Program had adopted essentially the recommendations involved in the resolutions.

The House adjourned sine die at 4:45 p. m.

OFFICIAL NOTES

RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company entitled "Your Health" will begin Wednesday, October 19, and run consecutively for thirty-six weeks. The program will be broadcast over the Blue network of the National Broadcasting Company each Wednesday at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).

These programs will be broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The programs to be broadcast in the first group, together with their dates and their topics, are as follows:

October 19. What Is Health?
October 26. Growing Strong.
November 2. Seeing and Hearing Well.
November 9. Healthier Boys and Girls.

The following is a list of the stations connected with the Blue network of the National Broadcasting Company, but no assurance can be given as to how many of these stations will broadcast the program "Your Health":

CORRECTION

New Officers of the Auxiliary.—In the list of officers elected by the Woman's Auxiliary to the American Medical Association for 1938-1939, published on page 1109 of THE JOURNAL September 17, the name of the chairman of organization, Mrs. Frank N. Haggard, 615 East Olmos Drive, San Antonio, Texas, was inadvertently omitted.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

Dedication of Hospital for Indians.—The new \$450,000 building of the base hospital for Navajo and Hopi Indians, the Southern Navajo General Hospital and Sanatorium at Fort Defiance, was recently dedicated with Dr. James G. Townsend, Washington, D. C., director of health, U. S. Office of Indian Affairs, presiding. Dr. William W. Peter, medical director, Navajo-Hopi areas, Window Rock, spoke and Henry Taliman, chairman, Navajo Tribal Council, spoke for the Navajo tribe. A patriarchal ceremony by a representative of the Navajo medicine men preceded the dedication and official opening. E. R. Freyer, general superintendent of the Navajo Agency, officially opened the building. The old hospital is being used as a sanatorium for tuberculosis. The two buildings provide for 226 patients. The Navajo-Hopi reservation of 25,000 square miles is the largest of 199 Indian reservations in twenty-two states; it has a total population of about 45,000 Navajos and 3,000 Hopis. In this area there are ten hospitals with 344 beds and three sanatoriums with 129 beds. The hospital at Fort Defiance is to serve the entire Navajo-Hopi area through receiving difficult cases, maintaining a central laboratory service, training new appointees and by occasional area clinics and refresher courses. Dr. Paul C. F. Vietzke is medical superintendent.

CALIFORNIA

Plague Infection.—According to *Public Health Reports*, plague infection was proved in a pool of thirteen fleas from seven chipmunks collected July 14 at Cedar Crest Resort in the Sierra National Forest, 2 miles west of Lake Shore, Huntington Lake, Fresno County.

Personal.—Dr. Jacob C. Geiger, health officer of San Francisco, has been honored by the king of Italy with the Cross of Cavaliere of the Order of the Crown of Italy "for services of distinction in the field of public health."—Dr. Frank F. Barham, Los Angeles, publisher of the *Evening Herald and Express*, has been elected president of the University of Southern California Alumni Association.

Society News.—Dr. Wilson Stegeman, Crescent City, addressed the Humboldt County Medical Society in Eureka August 1 on "Prevention of Postoperative Complications by Giving of Glucose by Mouth Before Operations" and Dr. Norman N. Epstein discussed syphilis.—At a meeting of the Alameda County Medical Association, Oakland, September 19 the speakers were Drs. Leon I. Oppenheimer on "Urinary Symptoms in Women"; Charles B. Fowler, "Fractures of the Elbow," and Karl J. Deissler, "Medical Shock."—At a meeting of the Los Angeles Society of Ophthalmology and Otolaryngology with the Research Study Club of Los Angeles September 26 the speakers were Drs. Warren A. Wilson and David A. McCoy on "The Problem of Scientific Terminology in Eye Diseases" and Dr. William S. Kiskadden on "Plastic Surgery in the Region of the Eye."

COLORADO

State Medical Election.—Dr. John W. Ames, Denver, was chosen president-elect of the Colorado State Medical Society at its annual meeting in Estes Park September 8-10. Dr. Leo W. Bortree, Colorado Springs, was installed as president. Dr. John B. Hartwell and Dr. William A. Campbell Jr., both of Colorado Springs, were elected vice president and treasurer respectively. The next annual session will be held at Colorado Springs.

FLORIDA

Fifth Annual Clinical Conference.—The Florida section of the Southeastern Surgical Congress conducted its fifth annual clinical conference at the Florida State Hospital, Chattahoochee, August 27. Participating in the program were:

- Dr. William R. Meeker, Mobile, Surgical Lesions of the Right Lower Quadrant Stimulating Acute Appendicitis.
- Dr. Walter R. Holmes, Atlanta, Cervicitis.
- Dr. Walter C. Jones Jr., Miami, Acute Pelvic Conditions Before and After Treatment.
- Dr. Thomas C. Davison, Atlanta, Clinical Examination of Surgical Patients.

- Dr. James B. McLester, Birmingham, Clinical Examination in Cases of Nutritional Disturbances.
- Dr. James G. Lyerly, Jacksonville, Operative Treatment of Involuntary Insanity of Agitation Type.
- Dr. Wilfred McL. Shaw, Jacksonville, Roentgen Ray in Diagnosis of Some Surgical Brain Diseases.
- Dr. Frederick W. Wilkerson, Montgomery, Medical Aspects of Gall-bladder Disease.

ILLINOIS

Society News.—Dr. Edwin C. Ernst, St. Louis, discussed cancer before the Madison County Medical Society in Alton September 2.—Dr. Arthur E. Hertzler, Halstead, Kan., discussed the thyroid gland before the Sangamon County Medical Society in Springfield September 1.

Venereal Disease Control Officer.—Dr. Herman M. Soloway, Chicago, has been appointed venereal disease control officer of the state department of health. The newly created post was made possible by funds allotted to the state by the U. S. Public Health Service. Dr. Soloway graduated at the University of Illinois College of Medicine in 1922.

INDIANA

Building for State Board of Health.—Plans are under way to construct a building for the state board of health at the Indiana University Medical Center, Indianapolis. The building will be a modern office and laboratory structure of reinforced concrete construction faced with light colored brick and trimmed with Indiana limestone to harmonize with other buildings in the medical center.

Courses in Tuberculosis.—Sanatoriums throughout the state will be used as teaching centers in the short courses in tuberculosis to be sponsored again by the Indiana Tuberculosis Association. One afternoon and evening will be devoted to the work in each location. The purpose of the course is to acquaint physicians with the recent progress in the treatment of tuberculosis. The courses, which will be made up of round table discussions, presentation of clinical material and demonstrations, will be held in the following places:

- St. Edward's Hospital, New Albany, November 16.
- William Ross Sanatorium, Lafayette, September 9.
- Sunnyside Sanatorium, Oaklandon, October 12.
- Boehn Lake Health Hiller, Indianapolis, October 12.
- Boehn Lake Health Hiller, Indianapolis, October 13.
- Boehn Lake Health Hiller, Indianapolis, October 18.
- Boehn Lake Health Hiller, Indianapolis, October 15.

Committee to Study National Health Problems.—Dr. Herman M. Baker, Evansville, president, Indiana State Medical Association, has appointed a committee to study the present national situation as it relates to the future practice of medicine. Members of the committee, which will submit a report to the house of delegates of the state association at the annual meeting October 4-6, are:

- Dr. Cleon A. ... chairman, executive committee.
- Dr. Carl H. ... member, executive committee.
- Dr. Herman M. ... president.
- Dr. Edmund ... Wayne, president-elect.
- Dr. Maynard A. Austin, Anderson, chairman of the council.
- Dr. Frank M. Gastineau, Indianapolis, bureau of publicity.
- Dr. Norman M. Beatty, Indianapolis, chairman, legislative committee.
- Dr. Oliver O. Alexander, Terre Haute, counselor, Fifth District.
- Dr. Walter C. McFadden, Shelbyville.
- Dr. Alfred H. Ellison, South Bend.
- Dr. Roscoe H. Beeson, Muncie.
- Dr. Jacob T. Oliphant, Farmersburg.

Ex officio members are Drs. Arthur F. Weyerbacher, Indianapolis, treasurer; Eldridge M. Shanklin, Hammond, editor of the state association journal, and Albert Stump, Indianapolis, attorney for the association.

IOWA

State Interprofessional Program.—An interprofessional program will be held in Waterloo October 12 in conjunction with a meeting of the Iowa State Association of Registered Nurses. Varying views of the recommendations of the National Health Conference as they affect the professions will be presented. Right Rev. Monsignor Maurice F. Griffin, Cleveland, will discuss why the public will suffer if such a program is adopted.

District Meeting.—The fall meeting of the Iowa and Illinois Central District Medical Association will be held at the Blackhawk Hotel in Davenport October 7. Dr. Archibald L. Hoyne, Chicago, will speak on "Treatment of Some Common Contagious Diseases"; Dr. Charles G. Sutherland, Rochester, Minn., on "X-Ray Diagnosis and Interpretation," and Dr. Marius Nygaard Smith-Petersen, Boston, on an orthopedic subject. The motion picture "Diagnosis and Treatment of Syphilis" will be shown.

Graduate Courses.—In accordance with a new plan, representatives from each councilor district have been appointed to form a committee on postgraduate medical education to confer with and assist local physicians in selecting the type of graduate course they desire. In this way the speakers' bureau of the state medical society will be able to present courses planned by the physicians themselves. Courses covering various phases of medicine will begin early in October in West Union, Fort Dodge, Dubuque, Sheldon and Emmetsburg. Plans are under way also to offer refresher courses, which will be financed by federal funds.

KANSAS

Annual Registration Now Due.—Physicians licensed to practice medicine in Kansas are required to renew their licenses annually between July 1 and October 1 and to pay a fee of \$1 to the secretary of the board of medical registration and examination. The secretary must strike from the register of licensed physicians the names of all physicians who fail to pay their annual registration fees as required by law. Physicians whose names are so removed may be reinstated by paying the secretary \$5 and submitting to him satisfactory proof of moral fitness.

KENTUCKY

Society News.—Drs. Shelton Watkins and Adolph B. Loveman, both of Louisville, addressed the Jefferson County Medical Society, Louisville, September 19, on "Medical Treatment of Nasal and Sinus Infections" and "Mucous Membrane Lesions of Interest to the General Practitioner" respectively. —Dr. Karl N. Victor, Louisville, addressed the Louisville Eye and Ear Society September 8 on "Colds, Micro-Organisms and Vaccines." —Dr. William Barnett Owen, Louisville, addressed the Society of Physicians and Surgeons, Louisville, September 15 on "Intra-Articular Fractures of the Knee."

MARYLAND

Survey of Unregistered Births.—A survey of unregistered births in two rural counties on the Eastern Shore of Maryland was completed June 30 by the federal division of vital statistics in cooperation with the state department of health. Field work was done by A. W. Hedrich, Sc.D., chief of the bureau of vital statistics in Maryland, and C. G. Bennett, field agent of the federal division. According to *The Registrar*, the objectives were to ascertain why certain births were unreported, to secure suggestions for improving birth registration, and to develop a pattern for future research of a similar nature. Three types of formal schedules were used in recording interviews. One type was for families in which unreported births had occurred; one was for physicians and another for local registrars. As far as the investigators were able to tell, nearly half of the unreported births investigated were attributed to forgetfulness or neglect on the part of physicians. The results of the survey showed that about one third of the physicians interviewed were beyond reproach in the matter of reporting. Only 10 per cent were very poor. According to the report, suggestions for the improvement of birth registration made by persons interviewed were as follows: that every birth be attended by a physician or licensed midwife; that every birth be registered by the attending physician or midwife; that each month physicians and midwives submit to the county health officer a list of all infants delivered during the month; that certificates be completed at the bedside, and that a more convenient size of certificate be adopted.

MICHIGAN

Society News.—Dr. Harry J. Isaacs, Chicago, discussed jaundice before the Calhoun County Medical Society, Battle Creek, September 6.—Dr. Frederick A. Collier, Ann Arbor, addressed the Alpena County Medical Society July 28 in Alpena on surgery of the gastrointestinal tract.

Health Conference.—A health conference was held in East Lansing September 10, sponsored by the governor's study committee on social welfare relationships, the third of a series of assemblies. The meeting was held to "consider ways of having the government assist people to obtain through the practicing physicians a higher standard of medical care." The program included discussions of the following topics: purpose of the conference, preliminary report of committee on the medical needs of governmental relief clients, American Medical Association Survey in Michigan, economic factors of medical care, the national health picture, future plans, expansion of health services, medical care for the indigent, and insurance. The speakers included Governor Frank Murphy; Dr. Don W.

Gudakunst, Lansing, state health commissioner; Dr. Louis Fernald Foster, Bay City, secretary of the Michigan State Medical Society; William J. Norton, chairman, state welfare commission; Dr. Clifford E. Waller, assistant surgeon general, U. S. Public Health Service; Henry F. Vaughan, Dr. P.H., health commissioner of Detroit; Howard Hunter, regional director, WPA; Dr. Raymond G. Tuck, Pontiac, director, emergency relief administration of Oakland County; Dr. Ralph H. Pino, Detroit, chairman, committee on distribution of medical care, state medical society; Dr. Sarah S. Deitrick, field consultant, Children's Bureau; Fred Hoehler, director, American Public Welfare Association; Dr. Thomas K. Gruber, superintendent, Eloise State Hospital; Dr. Henry Cook, Flint, at that time president of the state medical society, and Albert E. Meder, Detroit. Others on the program were U. G. Rickert, D.D.S., Ann Arbor, and Dr. Robert B. Harkness, Hastings, president and secretary respectively of the advisory council, State Department of Health; Fred R. Johnson, general secretary, Michigan Children's Aid Society; Harry Kelly, Grand Rapids, and Dr. Henry A. Luce, Detroit, then president-elect of the state medical society.

MINNESOTA

Graduate Courses at Continuation Study Center.—Dr. William A. O'Brien, director of postgraduate medical education, University of Minnesota, Minneapolis, announces the following series of fall courses for the practicing physician:

Proctology, September 19-24.
Diseases of the Genito-Urinary Tract, September 19-24.
Diseases of Infancy and Childhood, September 26-October 1.
General Medicine, October 10-15.
Diseases of the Skin, October 31-November 5.
Tuberculosis, November 14-19.

The fee of \$25 for each course does not include living accommodations. Licensed physicians outside the state may also register. Additional information may be obtained from Dr. O'Brien or J. M. Nolte, director of the Center for Continuation Study at the university. Courses to run from January 1 to June 30 will cover the following subjects: ophthalmology, diagnostic roentgenology, diseases of bones and joints, neuropsychiatry, general surgery, diseases of the blood and blood forming organs, obstetrics (not including gynecology) and gastro-enterology.

NEBRASKA

Personal.—Seventy-five physicians attended a dinner in honor of Dr. Lincoln Riley, Wisner, in Norfolk, July 20, celebrating his fiftieth anniversary in the practice of medicine. Dr. Lucien Stark, Norfolk, was toastmaster and the speakers were Dr. John P. Lord, Omaha, Dr. Morris Nielsen, Blair, and George A. Eberly, Lincoln, associate justice of the Nebraska supreme court.

Annual Registration Now Due.—Physicians licensed to practice medicine in Nebraska are required by law to register with the Department of Public Welfare annually on or before October 1 and to pay a fee of \$1. A license expires if the licensee fails to register, but within the thirty days next following its expiration it may be revived by the payment of the registration fee and a penalty of \$1. If that is not done, an order of revocation is issued and thereafter the revoked license can be reinstated only on the recommendation of the board of examiners in medicine and on the payment of the renewal fees and penalty then due.

NEW YORK

Bacillary Dysentery in a Children's Camp.—One hundred and thirty-eight children had a mild form of bacillary dysentery in an outbreak in a children's camp recently, *Health News* reports. Evidence of pollution of the camp water supply was found during the eight days of the outbreak and raw milk used as part of the milk supply was also suspected as a source of the outbreak. In most instances recovery occurred in twenty-four hours.

Typhoid in a Trailer Tourist.—A woman member of a trailer tourist party was found to be suffering from typhoid at a camp site near Beechwood recently. The woman, said to be a resident of Providence, R. I., was isolated at the Jamestown General Hospital and other members of the party were under observation August 29, according to a newspaper report. The party had previously camped at various places in New York and at the time of the report the origin of the infection had not been traced.

Society News.—Drs. Loftus Laramour Bryan and Harold H. Dodds, Marcy State Hospital, Marcy, addressed the annual joint meeting of the Syracuse and Utica academies of medicine

at a meeting September 22 on "Latest Insulin Treatment of Dementia Praecox" and "Myasthenia Gravis" respectively.—Dr. Howard S. Jeck, New York, addressed the Medical Society of the County of Rockland at its summer meeting July 13 on newer methods of diagnosis and treatment of urologic conditions.—Dr. Benjamin W. Seaman, Hempstead, addressed the Nassau Surgical Society in Hempstead September 12 on "The Evolution of Surgery."—Dr. Dean D. Lewis, Baltimore, addressed the Medical Society of Westchester County, White Plains, September 20 on "Effect of Ovarian Hormones on the Breast, Pathologically and Normally."

New York City

Symposium on Chronic Pulmonary Diseases.—A clinical session of the Tuberculosis Sanatorium Conference of Metropolitan New York October 3 will be devoted to a symposium on "Sputum in Tuberculosis and Other Chronic Pulmonary Conditions." Speakers will be Drs. Harry C. Ballou, Montreal, Que., on "Physiologic Mechanism of Expectoration"; Max Pinner, New York, "Sputum in Tuberculosis and Chronic Pulmonary Conditions," and David T. Smith, Durham, N. C., "Fungi in the Sputum and Their Significance."

Program for Pneumonia Control.—The New York City Department of Health has announced a program for the coming pneumonia season, including scientific meetings, practical demonstrations and laboratory training. Each of the five county medical societies will have a meeting in November or December covering the important aspects of treatment with serum. Plans have been made with the cooperation of certain hospitals to hold informal bedside demonstrations for small groups of physicians under the leadership of the health department advisers, who will demonstrate the practical details of intravenous serum administration. Lectures and laboratory demonstrations have also been planned for laboratory directors and technicians. The cooperation of the health department and the medical societies in this program was arranged by a subcommittee of the Advisory Committee on Pneumonia Control for New York City.

NORTH CAROLINA

New Building at State University.—Construction has begun on a new medical building at the University of North Carolina, Chapel Hill, with a PWA grant of \$400,000. The building will be five stories high, of a southern colonial style

New medical building.

of architecture. The first floor will have the administrative offices and quarters for the division of public health. Other floors will be divided among the departments of anatomy, biologic chemistry, pathology, pharmacology, physiology, bacteriology and public health. Most of the fifth floor will be taken up by air conditioned animal quarters. Laboratories will serve not only the medical school but the undergraduate and the graduate schools. There will also be library space for 40,000 volumes, a reading room, a lecture room with a capacity of 250 and smaller seminar rooms. Part of the PWA grant will be used to enlarge the university infirmary to give room for a charity clinic to provide instruction of medical students in physical diagnosis in their second year. Dr. William deB. MacNider is dean of the medical school.

OHIO

Hospital News.—Mr. George P. Bugbee, assistant superintendent of the University of Michigan Hospital, Ann Arbor, has been appointed superintendent of the Cleveland City Hospital.

Graduate Program in Canton.—Four members of the faculty of the University of Pennsylvania School of Medicine, Philadelphia, will be the guest lecturers for the first annual Postgraduate Day of the Stark County Medical Society at the Courtland Hotel, Canton, October 12. The lecturers will be

Drs. Thomas Grier Miller, professor of clinical medicine; Isidor S. Ravdin, professor of surgery; Floyd E. Keene, professor of gynecology, and Baldwin H. E. W. Lucke, professor of pathology.

Fall Series of Lectures.—The Mahoning County Medical Society is sponsoring a series of lectures, which opened September 21 and will be given weekly until November 9. The speakers, all of Cleveland, are:

- Dr. Russell L. Haden, Treatment of Hemorrhagic Disease, September 21.
- Dr. Arthur Carlton Ernstene, Drug Treatment of Heart Disease, September 28.
- Dr. Ernstene, Management of Hypertension, October 5.
- Dr. Haden, Treatment of Anemia, October 12.
- Dr. Haden, Treatment of Leukemia, October 19.
- Dr. Everett N. Collins, Treatment of Peptic Ulcer, October 26.
- Dr. Collins, Management of Disorders of the Colon, November 2.
- Dr. Haden, Treatment of Arthritis, November 9.

PENNSYLVANIA

Hospital News.—The Lions Club of McKeesport, aided by several other organizations, recently made a campaign for funds to buy a respirator for the McKeesport Hospital. The clubs raised \$10,224, it is reported, of which \$3,000 was paid for the respirator and expenses of the campaign and \$7,500 was set aside for upkeep and emergency aid for persons unable to pay for care.

Fayette County Meetings.—The annual fall clinic of the Fayette County Medical Society will be held at the Uniontown Hospital, Uniontown, September 29, with Drs. Louis Hamman, associate professor of medicine, and William F. Rienhoff Jr., associate professor of surgery, Johns Hopkins University School of Medicine, Baltimore, as the guest speakers. A meeting of the society was held September 1 at the Connessville State Hospital, Connessville, with Drs. Domer S. Newill and Lucian Dale Johnson, both of the hospital staff, as the speakers on "Teratoma Testis Abdominis" and "Peptic Ulcer" respectively.

Pittsburgh

Society News.—The Allegheny County Medical Society met September 20 with the following speakers: Drs. Cyril F. Lauer on "Eye Lesions of Syphilis, Tuberculosis, Diabetes and Infective Endocarditis"; James R. Johnson, "Malignancies of the Uterus"; George J. Thomas, "Clinical and Laboratory Observations on Intravenous Anesthesia"; Wendell B. Gordon, "Recent Advancement in the Treatment of Heart Disease."

Course in Industrial Hygiene.—The postgraduate committee of the Allegheny County Medical Society and the department of industrial hygiene of the University of Pittsburgh School of Medicine have arranged a graduate course in industrial hygiene to be given at the medical school October 24-28. The first four days will be devoted to lectures by physicians and others on the university staff and associated with industrial firms in Pittsburgh as well as several out of town speakers. Problems to be covered include air pollution, physiologic effects of materials and processes commonly used in industry, physiologic effects of heat, effects of electricity on the human body and the study of human failure as a cause of accidents. Among the guest speakers announced are:

- Dr. William B. Fulton, director, division of industrial hygiene, state department of health, Harrisburg.
- Dr. Robert A. Kehoe, associate professor of physiology, University of Cincinnati.
- Dr. Roy R. Jones, surgeon, division of industrial hygiene, National Institute of Health, Washington, D. C.
- Commander Charles S. Stephenson, division of preventive medicine, Medical Corps, U. S. Navy, Washington, D. C.

The last day of the course will be devoted to visits to industrial plants, the Carnegie-Illinois Steel Company at Homestead, the Mine Safety Appliances Company, Pittsburgh, and the Westinghouse Electric and Manufacturing Company, East Pittsburgh. Registrations must be received by October 15, as the class is limited to forty-five physicians. The fee for the course is \$50.

SOUTH CAROLINA

Society News.—Dr. Charles G. Spivey, Columbia, addressed the Ridge Medical Society August 15 in Johnston on "Symptoms of Heart Failure in Hypertension."—Dr. Robert R. Jones Jr., Durham, addressed the Darlington County Medical Society, Darlington, August 11 on plastic surgery.—Drs. Bernyrd C. McLawhorn and Thomas Parker, Greenville, addressed the Greenville County Medical Society recently on management of hypertensive patients and nephritis, respectively.—Dr. Hugh H. Young, Baltimore, addressed the Columbia

Medical Society September 12 on "Medical and Surgical Aspects of Diseases of the Prostate" and Drs. George H. Bunch and Lucius Emmett Madden, Columbia, on "Acute Epidural Abscess of the Cord."

TEXAS

Fort Worth Medical and Surgical Clinics.—The Tarrant County Medical Society will present the Fort Worth Medical and Surgical Clinics September 27 at the Hotel Texas, Fort Worth. The speakers, who will give clinical lectures and conduct dry clinics, are: Drs. Arthur E. Hertzler, Halstead, Kan., John H. Musser, New Orleans, La., and Grandison D. Royston, St. Louis.

UTAH

Society News.—Dr. Amos Christie, San Francisco, addressed a special meeting of the Utah County Medical Society, Provo, July 18 on the uses of sulfanilamide and on congenital syphilis. He also conducted a pediatric clinic July 20.

State Health Association Meeting.—The first annual meeting of the Utah State Public Health Association was held at the University of Utah, Salt Lake City, August 30-31. The speakers were Drs. Milton J. Rosenau, professor of epidemiology, University of North Carolina School of Medicine, Chapel Hill; Lyman L. Daines, dean, University of Utah School of Medicine, Salt Lake City; Frederick T. Foard, San Francisco, regional consultant, U. S. Public Health Service, and Edith P. Sappington, San Francisco, regional consultant, Children's Bureau. Dr. Louis E. Viko, formerly health officer of Salt Lake City, is president and Dr. Daines, president-elect. The association was organized Nov. 13, 1937.

VIRGINIA

State Medical Meeting at Danville.—The sixty-ninth annual session of the Medical Society of Virginia will be held in Danville October 4-6 at the Hotel Danville. Speakers at the general sessions will be:

- Dr. William J. Mallory, Washington, D. C., Diagnostic Value of the Clinical Aspects of Digestive Diseases.
- Dr. Frederick A. Willius, Rochester, Minn., Effects of Protracted and Recurrent Congestive Heart Failure on the Liver.
- Dr. Robert Finley Gayle Jr., Richmond, Problem of Caring for the Mentally Sick in Virginia.
- Dr. Reuben F. Simms, Richmond, Value of Periodic Health Examinations.
- Dr. James Franklin Waddill, Norfolk, Clinical Manifestations of Acute Rheumatic Fevers: Age Incidence, Diagnosis and Treatment.
- Dr. Emmett Triple Gatewood, Richmond, Diagnostic Methods Which Have Served Me Best in Determining Sinus Disease and So-Called Hay Fever.
- Dr. Karl S. Blackwell, Richmond, Some Practical Considerations of the Sinuses.
- Dr. David C. Wilson, Charlottesville, Shock Therapy in the Treatment of Affective Disorders.
- Drs. Julian R. Beckwith, James Edwin Wood Jr., and Byrd S. Leavell Jr., Charlottesville, The Clinical Course, Treatment and Prognosis of Acute Glomerulonephritis.
- Dr. William P. Gilmer, Clifton Forge, Roentgen Ray Examination of the Colon.

The Woman's Auxiliary will hold its sixteenth annual meeting at the same time and will be addressed by the president of the state medical society, Dr. George F. Simpson, Purcellville; the president-elect, Dr. Alex F. Robertson Jr., Staunton; the president of the Danville-Pittsylvania Academy of Medicine, Dr. Perry W. Miles, Danville, and the chairman of the advisory council, Dr. Philip St. L. Moncure, Norfolk. Other societies that will meet during the week are the Virginia Radiological Society, Virginia Pediatric Society, Virginia Neuropsychiatric Society and Virginia Obstetrical and Gynecological Society.

WEST VIRGINIA

Society News.—Drs. Robert W. W. Phillips and Delivan A. MacGregor, Wheeling, addressed the Central West Virginia Medical Society, Webster Springs, August 13, on common skin diseases and modern treatment of pneumonia, respectively.—Dr. Rosco G. Leland, Chicago, director, Bureau of Medical Economics, American Medical Association, Chicago, addressed the Kanawha Medical Society, Charleston, September 13, on "The National Health Conference."—Drs. George W. Crile, George Crile Jr. and Ernest Perry McCullagh, Cleveland, will address the Parkersburg Academy of Medicine October 5 on "Clinical Aspects of Endocrinology."—Dr. Arthur E. McClue, state health commissioner, Charleston, will address the Ohio County Medical Society, Wheeling, September 30 on "Socialized Medicine."

WISCONSIN

Premature Feeding and Nursing Bureau.—The Medical Society of Milwaukee County has established a "premature feeding and nursing bureau" in cooperation with the Visiting Nurse Association at St. Joseph's Hospital. The bureau includes a nursery with special equipment and a mother's milk station under the supervision of Miss Alberta Boon, whose salary is provided by the Visiting Nurse Association. She and her staff will investigate facilities for caring for premature infants, instruct mothers in their care in the home, aid physicians and oversee safe transportation of such infants to hospitals when necessary. The Milwaukee Lions Club has donated a refrigerator for storing milk. The breast milk collected will be sold to those able to pay and given free to the indigent. Physicians are requested to inform the bureau as soon as possible after the birth of a premature infant. Other hospitals will be accepted for participation in the project as soon as they conform to minimum standards, according to the *Milwaukee Medical Times*. Dr. Robert E. McDonald is chairman of the society's public nursing committee, under whose direction the new bureau was developed.

WYOMING

Society News.—Rev. Alphonse M. Schwitalla, Ph.D., dean, St. Louis University School of Medicine, St. Louis, addressed the Natrona County Medical Society at a special meeting in Casper August 15 on medical care as proposed at the National Health Conference.

Plague Infection.—According to *Public Health Reports*, plague infection was proved in tissue from two ground squirrels (*Citellus armatus*) shot July 9 and from one shot July 22; in a pool of forty-one fleas from one ground squirrel and a pool of twenty-nine lice and three ticks from two shot July 9; these specimens were collected from 6 to 8 miles northeast of Cokesville. It was also proved in the following specimens collected July 20-21 in the vicinity of Hamsford: 129 fleas from thirty-nine ground squirrels, a pool of 147 fleas from seventy-four ground squirrels and in a pool of 101 fleas from forty-nine ground squirrels. The disease was also found to be present in a pool of forty-two fleas and four lice from eighteen ground squirrels shot July 25, 2 miles south of Cora, Sublette County.

GENERAL

Rocky Mountain Medical Conference.—The biennial Rocky Mountain Medical Conference will be held at the Hotel Utah, Salt Lake City, Sept. 5-7, 1939. Scientific sessions will be held on the campus of the University of Utah.

Casselberry Fund Prize Available.—The sum of \$500 has accrued from the Casselberry Fund, administered by the American Laryngological Association, and is now available for a prize award, decoration or the expense for original investigation or research in the art and science of laryngology and rhinology. Theses or reports of work done must be in the hands of the secretary, Dr. James A. Babbitt, 1912 Spruce Street, Philadelphia, secretary of the association, before February 1 of any given year. Any further information desired will be furnished by Dr. Babbitt.

Gift for Syphilis Campaign.—A special program of education in syphilis control and social hygiene will be inaugurated October 1 by the American Social Hygiene Association, made possible by an anonymous gift of \$25,000. The program will attempt not only to bring knowledge of venereal disease before youth but also to provide biologic information and guidance in preparing young men and women for stronger and more enduring marriage and family relations, it was said. This gift brought the total contributed to the fund being raised by the association's national antisiphylis committee to \$155,015.

Society News.—Dr. William H. Schmidt, Philadelphia, was chosen president-elect of the American Congress of Physical Therapy at its annual meeting in Chicago September 12-15. Dr. Frank H. Krusen, Rochester, Minn., was installed as president and Dr. Walter S. McClellan, Saratoga Springs, N. Y., was elected to the group of five vice presidents. Dr. Richard Kovacs, New York, was reelected secretary and Atlantic City, N. J., was chosen for next year's meeting place.—Dr. Wright Clarkson, Petersburg, Va., was elected president of the American Association for the Study of Neoplastic Diseases at the annual meeting in Washington, D. C., September 8-10. Dr. Rollin H. Stevens, Detroit, was elected vice president and

Dr. Eugene R. Whitmore, Washington, reelected secretary. —The annual meeting of the Mississippi Valley Medical Association will be held in Hannibal, Mo., September 28-30.

WPA Bibliography on Medical Cooperatives.—The Works Progress Administration is preparing a comprehensive bibliography of material relating to medical cooperatives. The project, which has been in progress since April 1937, is under the direction of Prof. Bernard Ostrolenk of the College of the City of New York, with the Cooperative League of the United States as a cooperating agency. All references to medical cooperatives, with an abstract of the contents of each book and article listed, will be included in the bibliography. The objective is to bring together an exhaustive compilation of references to cooperatives of every kind in all languages. The section dealing with medical cooperatives will include the translation into English of a large number of articles, particularly from Swedish and Danish. Drawing conclusions or offering recommendations will be carefully avoided. An encyclopedia of the cooperative movement is also being prepared, to contain between five and six hundred articles in condensed form. More than ninety WPA workers, chiefly with professional and technical background, are assigned to the work under way in New York City. To date more than 16,000 separate entries have been made in libraries and transcribed on index cards, and more than 15,000 abstracts of this material have been prepared. It is expected that the first volume of the bibliography will be ready for publication by January 1939.

Academy of Ophthalmology and Otolaryngology.—The forty-third annual meeting of the American Academy of Ophthalmology and Otolaryngology will be held in Washington, D. C., at the Hotel Mayflower October 10-14, under the presidency of Dr. Harry S. Gradle, Chicago. After Monday the mornings will be given over to instructional courses. Monday morning there will be a joint session at which a symposium on "Dermatological Lesions About the Eyes, Ears, Nose and Throat" will be presented by Drs. Robert von der Heydt, Chicago; Frederick A. Figi, Rochester, Minn., and Udo J. Wile, Ann Arbor, Mich. Among speakers at the section meetings in the afternoons will be:

- Prof. Mulock Houwer, Batavia, Java, Ocular Diseases Encountered in the Dutch East Indies.
- Prof. M. E. Alvaro, São Paulo, Brazil, Snake Venom in Ophthalmology.
- Dr. Horace Newhart and Henry E. Hartig, Ph.D., Minneapolis, Hearing Aids.
- Dr. Karl M. Houser, Philadelphia, Therapeutic Uses of Sulfanilamide in Ophthalmology-Otorhinolaryngologic Work.
- Dr. Mervin C. Myerson, New York, The Technic of Laryngofissure for Cancer of the Larynx.
- Dr. Lyle S. Powell, Lawrence, Kan., Practical Use of Homatropin-Benzedrine Cycloplegia: A Further Report.
- Dr. Algernon B. Reese, New York, Operative Treatment of Radiation Cataract.
- Dr. William H. Stokes, Omaha, Neb., Transplantation (Implantation) of the Lacrimal Sac in Chronic Dacryocystitis.

Wednesday afternoon the section on otolaryngology will have a panel discussion on sinusitis with the following speakers: Drs. Ernest M. Seydell, Wichita, Kan.; Richard A. Kern, Robert F. Ridpath and Harry P. Schenck, Philadelphia; Alexander S. Macmillan, Boston; Andrew A. Eggston and Duncan MacPherson, New York; Frank J. Novak Jr., Chicago, and Frederick T. Hill, Waterville, Maine. The teacher's section will hold its annual dinner meeting Monday evening. The guests of honor will be the surgeons general of the U. S. Army, U. S. Navy and U. S. Public Health Service, Major General Charles R. Reynolds, Admiral Perceval S. Rossiter and Dr. Thomas Parran and their wives. The president's reception will be held at the Mayflower Sunday afternoon October 9, the alumni dinners Tuesday evening, the annual banquet Wednesday evening and the annual golf tournament Friday afternoon. Gen. Wallace Dewitt, commandant of Walter Reed Hospital, has arranged for a visit to the hospital Friday afternoon.

Conference on Rural Medicine.—A conference on rural medicine will be held October 7-8 at the Mary Imogene Bassett Hospital, Cooperstown, N. Y., under the auspices of the staff. Dr. Haven Emerson, New York, will preside at a session on rural morbidity at which the speakers will include Drs. George M. Mackenzie, Monroe A. McIver, John H. Powers, Francis F. Harrison and David M. Kydd of the hospital staff; Dr. Edwin L. Crosby, associate in biostatistics, Johns Hopkins University School of Hygiene and Public Health, Baltimore, and Joseph V. DePorte, Ph.D., state department of health, Albany, N. Y. Dr. Edward S. Godfrey Jr., state health commissioner of New York, Albany, will preside over a section on "Health Department Programs and School Health Programs in Rural Areas"; the speakers will be Dr. Emerson, Dr. Allen W. Freeman, professor of public

health administration, Johns Hopkins University School of Hygiene and Public Health, and Dr. Marjorie F. Murray of the hospital staff, Cooperstown. At a session on "Postgraduate Medical Education in Rural Areas" Dr. Thomas P. Farmer, chairman of the council committee on public health and education, Medical Society of the State of New York, Syracuse, will preside. The speakers will be Drs. James D. Bruce, Ann Arbor, Mich., and John B. Youmans, Nashville, Tenn. Saturday morning's program will be on "Economics of Rural Medicine," with Mr. Owen D. Young, chairman of the board, General Electric Company, New York, presiding. The speakers will be:

- Dr. Vane M. Hoge, U. S. Public Health Service, Washington, D. C., Hospitals and Hospitalization in Rural Communities.
- Dr. Lloyd C. Warren, Franklin, N. Y., The Economics of Rural Medicine from the Viewpoint of the Country Doctor.
- Dr. Charles C. McCoy, Cooperstown, Rural Medicine and Economics.
- Michael M. Davis, Ph.D., New York, Economics of Rural Medicine.
- Dr. Rosco G. Leland, Director, Bureau of Medical Economics, American Medical Association, Chicago, Medical Care for Rural America.

CANADA

Lectures on Nutrition.—Through the committee on nutrition of the Canadian Medical Association, a series of lectures on nutrition is being presented before medical groups and the public in various parts of Canada. Sir Edward Mellanby, secretary of the Medical Research Council of Great Britain, will speak at Queen's University, Kingston, Ont., October 5. He will make public addresses at Ottawa, Ont., October 6, Toronto October 12, and Montreal October 13 or 14. Dr. Louis H. Newburgh, professor of clinical investigation and internal medicine, University of Michigan Medical School, Ann Arbor, Mich., has addressed meetings of the provincial medical associations at Calgary, Alta., Victoria, B. C., Regina, Sask., and Winnipeg, Man., during September. In addition he has given a number of public addresses on "Normal Nutrition."

Government Services

New Executive Director of Social Security Board

Oscar M. Powell, San Antonio, Texas, regional director of the Social Security Board, has been appointed executive director to succeed Frank Bane, who resigned to become executive director of the Council of State Governments, Chicago. Mr. Powell, a lawyer, has served as chairman of the Bexar County relief committee, administering local and federal relief, and as chairman of the Texas Regional Labor Board.

Technicians Wanted for Public Health Service

Open competitive examinations for positions in the U. S. Public Health Service as senior medical technician, assistant medical technician for bacteriology, roentgenology or the two subjects combined and medical technician for stethography and electrocardiography are announced. The salary for the first position is \$2,000 a year, for the second \$1,620 and for the third \$1,800. Applications must be on file with the U. S. Civil Service Commission by September 26; by September 29 if from Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington or Wyoming. Application forms may be obtained from the secretary of the board of civil service examiners at any first class postoffice and from district offices in Atlanta, Boston, Chicago, Cincinnati, Denver, New Orleans, New York, Philadelphia, Seattle, St. Louis, St. Paul, San Francisco, Honolulu, Balboa Heights, C. Z., and San Juan, P. R.

CORRECTIONS

Date of Death of Osler.—In an item in *THE JOURNAL*, September 10, page 1027, under Foreign News, reference was made to a meeting "on the eighty-ninth anniversary of the death of Sir William Osler." Obviously the anniversary referred instead to the birth of Sir William, who died Dec. 29, 1919.

Chief of Service at Research and Educational Hospital.—In the Educational Number of *THE JOURNAL*, August 27, page 840, under surgery, E. Oldberg was listed as chief of service at the Research and Educational Hospital, Chicago, whereas Dr. Warren H. Cole has been chief on the service at that hospital since September 1936.

Research on Asthma

The report of the Asthma Research Council shows that much important work has been done in the past year. At the asthma clinic of St. Mary's Hospital most of it has been in connection with hay fever, which is held to be so closely related to the asthma-urticaria group that deductions can be made from one as to the others. The pollen of any one of the English grasses has been found to serve as a diagnostic agent for all hay fever, and similarly a vaccine made from one grass will desensitize all hay fever. Even the pollen of exotic and very unusual grasses, such as bamboo and sugar cane, conformed to this rule. With the pollen of sugar cane being used as an antigen, it was found possible to desensitize completely a bad case of English hay fever. Such tests show the homogeneity of the pollen antigen and the uselessness of testing patients with a long series of grass pollens to find "which one is causing the mischief."

Several cases were investigated in which a bacterial focus of infection had been complicating and adding to the symptoms produced by grass pollen. But most of the subjects of hay fever were perfectly healthy and therefore the question did not arise. But when there was marked toxemia from a septic focus, this had to be taken into account in grass pollen desensitization. This phenomenon has an important bearing on the whole question of asthma and allied diseases.

The mental attitude of patients suffering from asthma became of increasingly obvious importance as the years went by, but this did not diminish the significance of the other factors. Unquestionably some emotional disturbance, even hilarity, accompanied by hearty laughter, might precipitate an attack of hay fever. The attacks at midsummer often made the patient more neurotic than during the ten safe months of the year. Thus there is a vicious circle; an emotional disturbance may start an attack and an attack may set up a neurosis.

BREATHING EXERCISES

In the asthma clinic at King's College Hospital it was found that all persons who have suffered from asthma for any length of time tend to develop a wrong way of breathing, which increases the functional disability of the lungs. Remedial exercises to promote proper breathing are therefore a treatment applicable to every asthmatic person. To be of use these exercises must be properly taught and practiced conscientiously. The results obtained were as follows: In about 40 per cent of the cases the asthma either disappeared or became so slight as not to inconvenience the patient. In about 30 per cent the condition was much improved and there remained about 30 per cent of failures. But of this last group about half had not learned to breathe properly, either because they could not pick up the knack or would not make enough of effort. There thus remained about 15 per cent who did not improve in spite of acquiring perfect breathing. These patients, who were selected for research on the clinical value of breathing exercises, carried on in their usual environment. They did not avoid feathers, dust or foods to which they might be sensitive, nor did they have vaccine treatment or nasal operations.

Copies of the report can be obtained free from the Asthma Research Council, King's College, Strand, London, W. C. 2.

Headache Associated with Intracranial Tumors

The headache of intracranial tumors is generally attributed to increased intracranial pressure. An investigation of a series of cases in the department of neurosurgery of the London

Hospital by W. C. Northfield, a report of which has been published in *Brain*, shows that the headache cannot be so explained and traces it to a vascular origin. This headache has a predilection for the morning, usually occurring immediately after awakening but often wakening the patient at an early hour. Rising from bed makes it much worse, and sudden change of posture is much resented. Movements of the head are liable to increase or precipitate the headache. One form of headache is pathognomonic of intracranial tumor: the pain is generalized, paroxysmal and agonizing, and not infrequently it ends in semiconsciousness. This pain may last from thirty seconds to half an hour, then disappearing as quickly as it came and leaving the patient exhausted. There may be amnesia of this attack. The headache of intracranial tumor is nearly always referred to the forehead, whether it involves other areas or not.

THE INTRACRANIAL PRESSURE

In sixty-three of 102 verified cases of intracranial tumor Northfield found that the pressure exceeded the normal of 100-200 mm. The highest pressure was 700 mm. Many of the patients with a normal or subnormal pressure had severe headache and, on the other hand, in some cases in which the pressure was very high headache was absent. Therefore high pressure in itself is not a cause of the headache. These considerations cast doubt on the commonly accepted view that the headache associated with intracranial tumor is due to stimulation of the dura by increased intracranial pressure. Unilateral headache cannot be so explained. The differences in pressure within various parts of the brain when a tumor is present must be very small, for the brain, being so soft, is immediately displaced from an area of high to one of lower pressure.

THE VASCULAR ORIGIN OF THE HEADACHE

Consideration of conditions other than tumor suggest that the headache may be of vascular origin. The sudden severe pain which heralds subarachnoid hemorrhage may be felt in or over one eye, and at the necropsy the aneurysm is found on the same side of the head. This suggests that the gradual stretching of the wall of the artery and the final rupture of the aneurysm may set up a train of afferent stimuli which is interpreted as headache. In the following case it is difficult to avoid the conclusion that the headache was of vascular origin: A woman aged 41 suffered from right frontal headache and developed right oculomotor palsy. Aneurysm of the right communicating artery was diagnosed and was confirmed by arteriography. The right internal carotid artery was ligated. Half an hour after the operation she acquired a dull ache on the right side of the forehead, similar to what she previously felt. It was easier when she sat up and was aggravated on lying flat. Evidently the interference with the blood supply flow by the ligature provoked afferent stimuli similar to those provoked by the aneurysm. Another proof of the vascular origin of headache is that it is produced by intravenous injection of histamine, which causes dilatation of the cerebral vessels.

The Registration of Stillbirths

It is curious that while stillbirths are registered in Scotland they are not in England and that the only other countries where this holds are Ireland and Palestine. In the House of Lords when supporting the second reading of a bill for registration in England Lord Dawson (ex-president of the Royal College of Physicians) said that in these days of a smaller birth rate we needed to do everything possible to secure that the babies born were of the best. Every baby which died represented a failure and we could discover the cause only by studying the whys and wherefores of the failures. In 1934, 43,670 infants died in England at or soon after birth, and it was estimated that 4,000 died in Scotland in 1936. Civilization had brought down the death rate but it had also brought down the birth rate. No

one wanted a hopeless infant to survive, but a number of potentially fit children were lost by want of knowledge and care. It occurred in all classes of the community and was not connected with a particular state of life or society and therefore was probably in large part due to lack of knowledge. He recommended a close study of selected groups of children with the aid of the research department.

Hospital Isolates All Fever Cases of Doubtful Diagnosis

Complete isolation for every incoming patient, to prevent the spread of disease, has been achieved in the new block of the London Fever Hospital. When the original hospital was built in 1801 the idea was to have a current of air circulating under and around the building. The next step was a building consisting of separate rooms, each isolated from the other. Now in the new block each patient will be isolated. It will be used as a clearing house for incoming patients whose disease has not been definitely diagnosed.

Increased Production of Opium

The report of the special committee of the League of Nations on the cultivation and manufacture of opium appears in the August 15 *Siècle médical*. This committee was appointed to ascertain whether the cultivation of the poppy from which opium is made as well as the production of this narcotic and its derivatives could not be limited and controlled. One hundred and forty-five annual reports from various countries were examined. These reports are encouraging so far as new legislation is concerned. Several countries have announced the passage of new laws or modifications of existing ones to comply with their international obligations in the struggle against the clandestine manufacture of opium. The report from the United States showed that the number of addicts had been reduced from an average of one per thousand of the population as it existed a few years ago to an average of two or three per 10,000, varying according to individual states. The total number of addicts in the United States is estimated at from 30,000 to 50,000 at the highest. In Canada the number of addicts has fallen from 8,000 (ten years ago) to 4,000 at present. The committee found that since 1931 there had been a marked reduction in the manufacture of the five principal habit-forming drugs, viz., morphine, diacetylmorphine, cocaine, codeine and ethylmorphine hydrochloride. There is no longer an excess of legitimate manufacture to form a source of supply for addicts. The 1936 statistics show a general marked increase, however, both in production and in consumption of morphine converted into other forms of narcotics. This increase was interpreted by the committee as the result of a constantly increasing demand of a military character. The manufacture of opium, which in 1935 was 30.8 tons, rose to 36.8 tons in 1936, that of codeine rose from 19.9 tons to 24.3 tons, that of ethylmorphine hydrochloride, from 1,850 Kg. to 2,600 Kg. and that of diacetylmorphine from 670 Kg. to 870 Kg. The quantity of morphine converted into other drugs underwent a marked increase in 1936, rising from 22 tons in 1935 to 28 tons in 1936. The clandestine sale has decreased in certain countries, particularly the United States and Canada. Cooperation between the police of different countries has been efficient.

The committee studied the introduction of hitherto neglected measures to control more rigidly the passports of persons engaged in the sale of narcotics as well as to provide stricter surveillance of transport by airplanes and steamships. The Chinese delegate stated that his government had determined to apply the six year plan of suppression of the cultivation of the opium poppy in nonoccupied territory and to use every means to fight the abuse of and illicit traffic in narcotics. The

cultivation of the opium poppy could be greatly reduced as to the area allowed for such a purpose in the territory still under Chinese control, but the Japanese had compelled the inhabitants of the island of Quemoy, near Amoy, not only to cultivate the opium poppy but to establish a factory for the extraction of opium. The delegate from the United States stated that the civil government established by the Japanese in the province of Hopei had abrogated the laws to govern the cultivation and manufacture of opium which had been enforced by the Chinese. In northern China there had been a marked increase in the use of opium since Japanese occupation. The opium manufacturers had at their disposal unlimited quantities of morphine which came from Chinese provinces under control of the Japanese and from Iran. The gravity of the situation was shown by the fact that 650 Kg. of diacetylmorphine had been sent to the United States in fifteen months. In Shanghai, except in the French and International concessions, all control had ceased. More than 1,000 cases of opium from Iran were being held at Macao for the Japanese to be sold in Shanghai or South China.

The Japanese member of the committee not only questioned the accuracy of the reports made by the Chinese and American delegates but denied some of them absolutely. The Japanese government had remained faithful to its policy of suppression of the abuse of opium and other habit-forming drugs and had continued to cooperate with the committee, even though no longer a member of the League of Nations. In Manchukuo the government had expelled 6,000 people engaged in opium traffic and was considering a plan to suppress cultivation of the opium poppy over a period of ten years. It was very difficult to eliminate the opium habit in China, because at the end of 1936 there were over 3,600,000 addicts.

At the end of the meeting the committee of the League of Nations passed the following resolution: 1. The attention of the council of the League of Nations is again drawn to the gravity of the situation as reflected in the reports submitted to the committee on narcotics. 2. The council is urged to demand more energetic measures on the part of all governments to correct the situation. 3. The reports should be sent to the Japanese and Chinese governments so as to have their views as to whether the information given by the Chinese and American delegates is accurate.

Treatment of Tuberculous Peritonitis

At the recent eighth annual Congress of Thalassotherapy, a conference founded to study the results of nonoperative methods, especially the influence of sea air and baths, in the treatment of tuberculous infections, a series of papers were read on the treatment of tuberculous peritonitis in children. It was concluded that, from the standpoint of pathogenesis, the disease is most frequently of genital origin in girls, that it is most common in both sexes as intestinal tuberculosis and that the first evidences are often found in the vicinity of tuberculous mesenteric lymph nodes. Stress must be laid on the relative frequency of an acute onset, the clinical picture greatly resembling that of peritonitis due to ordinary pyogenic bacteria or to the typhoid bacillus. The treatment should have as its basic principle a combination of heliotherapy and use of sea water baths. These methods are contraindicated only if associated active pulmonary lesions exist, but these are comparatively rare. If they do exist, early operative intervention is indicated. If such associated foci can be excluded, it is advisable to postpone operation as long as possible. Heliotherapy combined with treatment with sea air and sea water baths will often effect a cure without operation, which should be done only if there are no signs of improvement after a year of nonoperative treatment. Even if operation is indicated, the patient is in better condition to benefit by surgical measures after a year of such treatment. Ascites which is steadily increasing

in spite of tapping at regular intervals is an indication for early operative intervention, as are signs of intestinal occlusion. As soon as the ascites has disappeared and there are general signs of healing of the tuberculous peritonitis, removal of tuberculous intestinal or tubal foci is advisable. After apparent cure of tuberculous peritonitis, the patient should be given follow-up heliotherapy and treatment with sea air and sea water baths.

The Increase in Cancer Mortality

The considerable increase in the absolute number of cancer deaths in all civilized lands is undisputed. It is likewise generally recognized that the aging of the population, improved diagnosis and other elements are important factors in this upward trend. Numerous sources of statistical error have also been studied. In several central European regions for which almost complete necropsy statistics are available, the observations are much more exact than in former years. This is especially true of certain of the larger European cities. Virtually all investigators whose observations are based on this reliable type of material arrive at the same conclusion, namely that the increase in cancer is essentially a result of an aging of the population. On the other hand, another group of investigators, led by the American statistician Hofmann, maintain that the increase in cancer mortality is actually proceeding at a swifter pace than the aging of the population. Dr. Haubold of the National Health Bureau has recently worked up in great detail a sufficiently sizable and reliable statistical material from ten large German cities having a total population of 9.4 millions. In all these cities conditions predisposed toward a superior accuracy of the data: necropsies were required by law, and the large number of thoroughly trained physicians available reduced to a minimum the likelihood of incorrect diagnosis.

In his survey, Haubold compares the statistics of one prewar decade (usually 1901-1910) with one postwar decade (either 1920-1930 or 1923-1932). The older age groups presented greater increases than the younger. The increase in the older male population was less than that in the older female population. Accordingly, although the aggregate population of the ten cities studied increased from 5.7 million to 9.4 million, namely by barely some 61 per cent, this by no means represents a symmetrical increase in all age groups of both sexes. The increase in the absolute number of cancer fatalities meanwhile proceeded at a vastly greater rate; the yearly average rose from about 5,850 to about 13,260, an increase of about 226 per cent. Careful study reveals that there was no question of an increased cancer mortality for either sex up to the sixty-ninth year of life. On the contrary, in most age groups a slight but appreciable decline in the mortality was evidenced. Only among the elderly of both sexes had the death rate from cancer increased, in some instances quite substantially. Here, however, could be observed definite interrelation of the rise of cancer mortality among the elderly and the decline in the considerable mortality from senile infirmities. Between the two decades compared, the latter rate declined 58.2 per cent among men and 53.8 per cent among women. Thus the greater than 50 per cent decline in mortality from senile infirmities is paralleled by a substantial simultaneous increase in cancer mortality among the identical age groups. From all the foregoing data one may conclude that the danger from cancer is no greater today than in former years. An inhabitant of one of the larger German cities is therefore no more likely to become affected with fatal cancer or to die of the disease at an earlier age than the average citizen of some forty years ago. A mounting fear of cancer is thus groundless.

Another related problem, likewise investigated by Dr. Haubold, is that of cancer morbidity among mothers. The card index records of about 3,000 women, assembled by the German National Anticancer Commission, were studied. It was disclosed that about three fourths (75.9 per cent) of all these women had been domestically occupied and that nearly half of this group were under the age of 60. Thus cancer must attack chiefly women who should still be leading active lives and even still youthful women, since 367 (11.8 per cent) were under the age of 40 at the time of clinical examination. Furthermore, it was revealed that the great preponderance of women included in this material presented cancer of the uterus, the breast and so on, and only 14.5 per cent cancer seated in the digestive tract. This distribution is, to be sure, probably the consequence of a somewhat homogeneous composition of the survey material, since it is chiefly drawn from gynecologic clinics. Moreover, about 14 per cent of these women had children whom they were unable to nurse. A social as well as a medical problem here poses itself. The detriment suffered by the children through the languishing illness of a cancerous mother is precisely the worst in the families of those women who should be best capable of looking after their own. This statistical study reveals that not altogether unfounded are the apprehensions of many physicians with regard to the genetic-biologic implication of a high cancer morbidity among women in what ought to be the age of greatest activity.

Surgical Treatment of Pulmonary Abscess

Professor Paolucci of Bologna, in a lecture before the Berlin Medical Society, reported his studies of 200 acute and chronic cases of pulmonary abscess observed during the last five years. The left lobe was the seat of the abscess in 70 per cent of the cases and the inferior lobe was involved in 46 per cent of all the cases. Difference of opinion still exists as to whether lung abscesses are of bronchial or embolic origin. Experiments conducted at Paolucci's clinic revealed that the pulmonary process can always (100 per cent of cases) be produced by the bronchial route if the coughing reflex in the upper nasal passages is abolished and that part of the bronchus superior to the introduced material is closed off. These experiments spoke against the embolic origin of pulmonary abscess.

Immediate surgical intervention is indicated in case of a septic gangrenous abscess which tends to run a rapid course. In the chronic type characterized by secondary fibrosis and bronchiectatic formations, one can set particular limits to the suppurative bronchiectasis. In the latter event nothing less than extirpation of the entire affected lung is indicated. A mixed bacterial flora is almost always found, the preponderance of a certain micro-organism being of no prognostic value; anaerobes too are frequently present. In contrast to the general opinion that six weeks of observation is necessary before prognosis of a benign or malignant course is possible, Paolucci believes that this determination can be made after two weeks on the basis of the patient's condition and from the roentgenogram. The author's therapeutic approach is governed by this principle; early surgical intervention is with him axiomatic. The simplest procedure consists in plugging of the opened abscess cavity; for this the author recommends gauze saturated with iodoform or barium suspension. In extensive septic gangrene, a condition frequently resistant to all treatment, a wide pneumotomy is still the operation of choice. Removal of the pulmonary tissue in stages has proved a successful substitute for the often difficult lobectomy. In cases of multiple abscesses the individual foci ought to be opened separately if they are far apart. Adjacent cavities heal best if a wide breach is created. Frequent and extremely severe complications are pleural reactions, empyema for example. Even for severe cases, if timely operation is performed, the mortality is only 14 per cent, as contrasted with cases which first come to

operation in the chronic stage; the mortality for the latter is 50 per cent. In the course of the illness apparent improvement may be observed, but this only serves to delude the physician and to postpone the necessary surgical treatment.

ITALY

(From Our Regular Correspondent)

Aug. 15, 1938.

Social Medicine

Regulations recently established require employers in agricultural and industrial fields to arrange periodic medical examinations at intervals of no more than six months for workers, especially women and children. The regulations concern types of work involving exposure to atmospheric changes, humidity, dust or irritating toxic gas or smoke, as well as those involving the transporting of heavy weights or the maintaining for long hours of an unnatural posture.

The Comitato tecnico nazionale di agricultural work met recently in Milan to discuss problems involving the health of workers during rice harvest and threshing. Professor Aiello spoke on sanitary statistics which were gathered during a recent campaign for the health of rice workers. He dealt especially with spirochetosis and certain forms of traumatic and cutaneous diseases which are frequent in workers during the time of mowing and husking. A competition among manufacturers of protective stockings, shoes, arm cuffs and glove fingers to be used by rice workers is announced.

The first national congress on living conditions of Italians in rural districts was recently held in Rome, with many hygienists and physicians in attendance. Professor Alessandrini shoyed the advisability of carrying on a campaign against brucellosis in rural districts. Professor Nai discussed bovine tuberculosis and echinococcosis. Professor Gardini dealt with ancylostomiasis. Professor Vennero discussed sanitation of rural housing, compulsory insurance of farmers against industrial diseases and use of proper implements in farming.

Regulations concerning medical service given to farmers were recently established. Medical honorariums and the cost of clinical and roentgenologic researches will be reduced.

Cancerigenic Substances

Professor Watermann of the Istituto del Cancro of Amsterdam addressed the members of the Accademia Medica of Rome on the cancerigenic properties of certain fatty substances by means of which he produced carcinoma of the stomach in rats. When the cholesterol esters are heated to a temperature of 200 C. they are transformed into cancerigenic substances, the prolonged administration of which, by mouth, induces the development of carcinomatous papilloma in rats. Daily administration of heated cholesterol esters for 260 or 350 consecutive days induced the formation of papilloma in two animals. The speaker said that there is not a chemical bond between various cancerigenic substances but that there may be a physiologic bond. He pointed out the importance of making studies on the action of many substances such as, for instance, food fats which are heated to high temperatures. In the discussion which followed, Professor Serono said that cholesterol oleate is harmless and has no cancerigenic action when it is prepared in a vacuum and well purified. However, when it is submitted to high temperatures in air it acquires cancerigenic properties because it is transformed during the reaction into tar products of the phenanthrene series, which are cancerigenic.

Avitaminosis in School Children

In a lecture before the Accademia delle Scienze Mediche of Naples, Professor Ciampi discussed the kinds of vitamin deficiency found in school children of Naples. The typical forms have the same importance as grave forms in relation to hygiene and prevention of infections. He makes a diagnosis of C

avitaminosis from the fragility of the capillaries, which is rapidly determined by a special vacuum cupping glass 1 cm. in diameter. The capillary resistance was diminished in forty-one children in a group of 137 who had the examination. It became normal in the majority of cases in about two weeks, during which time the children ate three oranges a day. Three oranges eaten daily also controlled avitaminosis C in a large group of young girls. The speaker questioned the mothers of avitaminotic children. He found that C avitaminosis is more frequent in poor than in rich families. When it develops in rich children it is due to errors in the diet.

Meeting of Dermatologists

The Società italiana di dermatologia e sifilografia held its thirty-first reunion in Rome with Professor Martinotti, head of the Bologna clinic, presiding. Professors Ciambellotti of the dermatosyphilopathic clinic of Modena, Sannicandro of the Sassari clinic and Ballarini of the dermatosyphilopathic clinic of Bologna were official speakers. Professor Ciambellotti spoke on focal dermatoses. The theory of focal infection is frequently objected to, especially because of the destructive operations frequently made on tonsils and teeth. The theory of the existence of focal dermatoses is also objected to. The speaker pointed out the difficulties which exist in ascertaining the role of dermatoses as foci of infection. It is possible that the pathologic skin may be a seat of infection. It is difficult, however, to establish the reflex, nervous or circulatory route followed by infection and the mechanism by which dermatosis may develop into a focus of infection. Professor Sannicandro spoke on the relation between focal infection and the urogenital apparatus. Gonorrhea is a typical focal infection which follows the characteristic evolution of other diseases of focal origin. Gonococci may enter the body, remain latent for a long time and increase in virulence late in the evolution of the infection. The syndromes with a focal origin in the lower segment of the genital tract are bacteriuria, diseases of the urinary tract, nonspecific orchiepididymitis, Reiter's syndrome and the so-called arthritic spirochetosis.

Professor Aldo Castellani, head of the clinic of tropical diseases, reported some cases of tropical mycetal urethritis. A group of professors of the clinic of Milan, of which Professor Pasini is the head, spoke on para-aminophenylsulfanilamide in the treatment of gonorrhea. Reference was made to 1,600 cases. The speakers regard para-aminophenylsulfanilamide of therapeutic value in the treatment of gonorrhea and its complications as well as in the treatment of soft ulcer and venereal adenitis. The inconveniences and phenomena of intolerance to the drug can be overcome by watching the patient carefully. The drug did not control gonorrheal vulvovaginitis in girls.

Marriages

THOMAS B. CARROLL JR., Waycross, Ga., to Miss Mildred Turner of Augusta, in Aiken, S. C., July 23.

JAMES LAFAYETTE HALL, Jackson, Miss., to Miss Eleanor Andrews Brown in Port Gibson, August 21.

WALTER EATON GARREY, Boston, to Miss Elizabeth Patten of Ann Arbor, Mich., in August.

CHAMPNEYS HOLT HOLMES to Miss Lena Jacqueline Swift, both of Atlanta, Ga., August 25.

FRANCIS W. HOULIHAN, Ackley, Iowa, to Miss Mary Agnes McLaughlin of Stuart, July 28.

JOHN S. HAIGH, Los Angeles, to Miss Margaret K. Neil of Pasadena, June 25.

IRVING L. GREENBERG to DR. REGINA GABLER, both of New York, August 27.

DUANE OLSON, Gaylord, Minn., to Miss Lyndis Iverslie of Delano recently.

GEORGE L. HOFFMAN JR., Philadelphia, to Miss Helen Mildred Lobb recently.

Deaths

Harold Dickinson Senior, Salsbury Cove, Maine; L.R.C.P., of London, and M.R.C.S., of England, 1892; University of Durham College of Medicine, Newcastle-upon-Tyne, England, 1895; F.R.C.S., England, 1895; since 1936 professor emeritus of anatomy at the New York University College of Medicine; after several years of teaching in England he spent several years in Canada and later served on the faculties of the Medico-Chirurgical College of Philadelphia and Syracuse University and spent three years as a fellow in the Wistar Institute of Anatomy and Biology, Philadelphia; in 1910 he was appointed professor of anatomy and director of the anatomic laboratories of New York University; was for many years an associate editor of the *American Journal of Anatomy*; member, and vice president 1922-1923, of the American Association of Anatomists; University of Durham in 1918 conferred on him an honorary degree and a gold medal; aged 67; died, August 6, in the French Hospital, New York.

Frederick Leonard Fenno • New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1917; fellow of the American College of Physicians; clinical professor of neuropsychiatry at the Louisiana State University School of Medicine; served during the World War; past president and secretary of the Orleans Parish Medical Society; formerly assistant professor of clinical neurology at his alma mater; for many years medical director of the public school system; aged 43; died, July 20, of cardiac dilatation and hypertension.

Roy Thaddeus Goodwin • San Antonio, Texas; University of Texas School of Medicine, Galveston, 1912; fellow of the American College of Surgeons; past president of the Bexar County Medical Society and the International Post Graduate Medical Assembly; on the staffs of the Robert B. Green Memorial Hospital, Santa Rosa Hospital, Nix Hospital and Baylor Hospital; aged 50; died, July 12, of a brain tumor.

Richard Hayward Morgan, Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1908; member of the Michigan State Medical Society; at one time on the staff of the Metropolitan Life Insurance Company Sanatorium, Mount McGregor, N. Y.; on the staffs of the Herman Kiefer Hospital, Harper Hospital and the Detroit Tuberculosis Sanatorium; aged 57; died, July 10.

Joseph William Dennin • Roselle, N. J.; Medico-Chirurgical College of Philadelphia, 1914, fellow of the American College of Surgeons; served during the World War; attending obstetrician to the Elizabeth General Hospital and St. Elizabeth's Hospital, Elizabeth, N. J.; aged 47; died, July 16, in the Veterans Administration Facility, Lyons, of tuberculosis.

Emanuel Friend • Chicago; Rush Medical College, Chicago, 1890; formerly instructor in surgery at his alma mater; fellow of the American College of Surgeons; for many years on the staff of the Michael Reese Hospital; co-editor of the fourth edition of "Principles of Surgery," by Dr. Nicholas Senn; aged 70; was found dead, July 19, of chronic myocarditis.

Robert Du Bose Alexander • St. Louis; Washington University School of Medicine, St. Louis, 1905; assistant professor of surgery, St. Louis University School of Medicine; fellow of the American College of Surgeons; served during the World War; on the staffs of St. Mary's and Jewish hospitals; aged 62; died, July 26, of cerebral hemorrhage.

Frank Kadlec • Chicago; Loyola University School of Medicine, Chicago, 1916; served during the World War; for many years attending physician to the Infant Welfare, Department of Health, City of Chicago; on the staff of the Jackson Park Hospital; aged 48; died, July 14, of pulmonary embolism and acute appendicitis.

Robert M. Adams, Ripley, Miss.; Memphis (Tenn.) Hospital Medical College, 1902; member of the Mississippi State Medical Association; president of the Mid-South Post Graduate Medical Assembly; formerly county health officer; aged 66; died, July 1, in the Baptist Hospital, Memphis, Tenn.

William Avery Hillard, Westerly, R. I.; College of Physicians and Surgeons, Medical Department of Columbia University, 1893; member of the Rhode Island Medical Society; for many years health officer of Pawcatuck, Conn., and school physician; aged 67; died, July 1, of Hodgkin's disease.

Russell Wilkins • Manchester, N. H.; Dartmouth Medical School, Hanover, 1896; veteran of the Spanish-American and World wars; for many years associated with the Veterans

Administration; aged 65; died, July 22, in the Elliott Hospital, of chronic bronchitis, emphysema and heart disease.

Walter Channing Bailey, Cambridge, Mass.; Harvard University Medical School, Boston, 1898; member of the Massachusetts Medical Society and the American Clinical and Climatological Association; served during the World War; aged 67; died, July 31, of cerebral hemorrhage.

William Isaiah Scott • Kokomo, Ind.; Medical College of Indiana, Indianapolis, 1898; formerly a druggist; served during the World War; formerly secretary of the Howard County Medical Society; at one time secretary of the county board of health; aged 63; died, July 1, of angina pectoris.

F. Marion Kent • Bellevue, Ohio; Medical College of Ohio, Cincinnati, 1889; fellow of the American College of Surgeons; past president of the Sandusky County Medical Society; formerly on the staff of the Bellevue Hospital; aged 73; died, July 10, of carcinoma of the prostate.

John Paul Roebuck • Lancaster, Pa.; Medico-Chirurgical College of Philadelphia, 1899; past president of the Lancaster City and County Medical Society; on the staff of the Lancaster General Hospital; aged 59; was instantly killed, July 2, in an automobile accident near Wilmington, Del.

James Alfred Bagley, Ensley, Ala.; Birmingham Medical College, 1903; member of the Oklahoma State Medical Association; formerly medical director of the Western Oklahoma Tuberculosis Sanatorium, Clinton, Okla.; aged 59; died, June 9, of carcinoma of the larynx.

John Alexander Hendrick • Shreveport, La.; University of Nashville (Tenn.) Medical Department, 1903; fellow of the American College of Surgeons; chief of surgical staff, Highland Sanitarium; aged 62; died, July 9, of coronary occlusion.

Joseph R. Ebersole, Monmouth, Ill.; Hahnemann Medical College and Hospital, Chicago, 1888; medical director of the Illinois Bankers Life Assurance Company; formerly member of the school board and county coroner; aged 78; died, July 29.

Henry Walton Mooney, New York; University of the City of New York Medical Department, 1891; member of the Medical Society of the State of New York; aged 76; died, July 17, of arteriosclerosis.

John B. Scruggs, O'Fallon, Ill.; St. Louis College of Physicians and Surgeons, 1898; member of the Illinois State Medical Society; past president of St. Clair County Medical Society; aged 71; died, July 4.

William Parsons Sawyer, Nevada City, Calif.; University of Pennsylvania Department of Medicine, Philadelphia, 1891; aged 74; died recently of mitral regurgitation and cardiac decompensation.

Charles Greene Brink, New York; University of the City of New York Medical Department, 1895; member of the Medical Society of the State of New York; aged 64; died, June 8.

Belle Ellingsen Merrill • Oakland, Calif.; University of California Medical School, San Francisco, 1920; aged 53; died, July 6, of injuries received in an accident near Coquille, Ore.

Lewis William Grice, Armada, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1918; aged 43; died, July 6, of illuminating gas poisoning, self administered.

Joseph Lieberman, East Rutherford, N. J.; Eclectic Medical College of the City of New York, 1909; aged 68; died, June 12, of coronary thrombosis and chronic myocarditis.

Creighton Walter Skelton • Providence, R. I.; Albany (N. Y.) Medical College, 1898; since 1924, business manager of the *Rhode Island Medical Journal*; aged 65; died, June 26.

William Parry Jones, Bethlehem, Pa.; University of Vermont College of Medicine, Burlington, 1890; aged 71; died, June 13, in St. Luke's Hospital, of chronic myocarditis.

Green Ewing Hill • Girard, Ill.; Rush Medical College, Chicago, 1890; past president of the Macoupin County Medical Society; aged 75; died, July 3, of heart disease.

Albert J. Weston, Cleveland; Western Reserve University Medical Department, Cleveland, 1889; aged 81; died, June 29, of cerebral hemorrhage and arteriosclerosis.

George Orrin Robbins, New Bedford, Mass.; Yale University School of Medicine, New Haven, Conn., 1879; aged 84; died, June 3, in Taunton, of arteriosclerosis.

Philip Maginis Johnson, Toledo, Ohio; Cleveland Homeopathic Medical College, 1899; aged 64; died, July 17, in St. Vincent's Hospital, of coronary sclerosis.

D. F. Hedgpeth, Ozark, Mo.; Missouri Medical College, St. Louis, 1888; aged 76; died, July 6, of cerebral hemorrhage.

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE: The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product.]

Slip-O.—George J. McCabe, trading as McCabe Drug Co., Fargo, N. D. Composition: Essentially water, sugar, menthol, chloroform and small amounts of pine tar and unidentified plant extractives. Fraudulently represented as a remedy for coughs, bronchitis, bronchial asthma, hay fever, catarrh, etc.—[N. J. 26727; July 1937.]

Life-Line Tonic.—John B. Kori, trading as United States Remedy Co., Jacksonville, Fla. Composition: Chiefly epsom salt, glycerophosphates, quinine, plant material, and citric and hydrochloric acids. Fraudulently represented as a "cure-all."—[N. J. 26732; July 1937.]

Protargol Vaginal Suppositories.—Paul B. Elder, trading as Paul B. Elder Co., Bryan, Ohio. Composition: Protargol, 1.18 per cent in each suppository. Adulterated because below the professed standard of strength and purity; misbranded because claimed to contain 5 per cent of protargol, and because fraudulently represented as a cure for gonorrhea in the female and effective to destroy the gonococcus.—[N. J. 26733; July 1937.]

Commanders.—Master Drugs, Inc., Omaha. Misbranded because of false and misleading claims, such as "Containing All Six Essential Vitamins A-B-C-D-E-G In Concentrated Form . . . Each Commander is equivalent in vitamin content to one spoonful Cod Liver Oil, one cake of yeast, one orange, two pounds of whole wheat . . ."—[N. J. 26734; July 1937.]

Solution of Genuine Doyle Chlorinometer Gas.—Chicago Drug Sales, Inc., Chicago. Composition: Chlorine dissolved in carbon tetrachloride. Fraudulently represented as a remedy for whooping cough, influenza, laryngitis, etc.—[N. J. 26735; July 1937.]

Universal Brand Pain Expeller.—Chicago Drug Sales, Inc., Chicago. Composition: Essentially ammonia, a pungent substance such as red pepper, a small amount of volatile oil, with alcohol and water. For rheumatism, neuralgia, stiff joints, etc. Fraudulent therapeutic claims.—[N. J. 26735; July 1937.]

Universal Brand Liniment.—Chicago Drug Sales, Inc., Chicago. Composition: Essentially an ammonium soap and volatile oils including camphor, with alcohol and water. Fraudulently represented to relieve rheumatism, sciatica, cramps, etc.—[N. J. 26735; July 1937.]

Laxative Cold and Grippe Breakers.—Chicago Drug Sales, Inc., Chicago. Composition: Acetanilid, starch and resinous plant material, coated with chalk. Fraudulent therapeutic claims.—[N. J. 26735; July 1937.]

Dr. Hobbs' Sparagus Kidney Pills.—Chicago Drug Sales, Inc., Chicago. Composition: Plant material including juniper berries. Fraudulently represented as a cure for kidney and bladder troubles, Bright's disease, dropsy, neuralgia, etc.—[N. J. 26735; July 1937.]

Eilert's Daylight Family Liver Pills.—Chicago Drug Sales, Inc., Chicago. Composition: Plant material including a laxative drug. Fraudulently represented as a cure for all fevers, blood impurities, female complaints, etc.—[N. J. 26735; July 1937.]

Kalamazoo Celery Nervine Blood and Liver Pills (or Dunkley's Celery-tone Pills).—Chicago Drug Sales, Inc., Chicago. Composition: Plant material including a laxative drug and an alkaloid-bearing drug. For blood, liver, kidney and stomach disorders, etc. Fraudulent therapeutic claims.—[N. J. 26735; July 1937.]

Knill's Black Diarrhea Blackberry Compound Pills.—Chicago Drug Sales, Inc., Chicago. Composition: Plant material including an alkaloid-bearing drug, a laxative drug and camphor. Fraudulently represented as a cure for black diarrhea, cholera, and all stomach pains. No blackberry present.—[N. J. 26735; July 1937.]

Bull's (Dr. John W.) Celebrated Pills.—Chicago Drug Sales, Inc., Chicago. Composition: Plant material including an alkaloid-bearing drug, and camphor. For impure blood, female complaints, liver and kidney disorders, anemia, etc. Fraudulent therapeutic claims.—[N. J. 26735; July 1937.]

Erie Drug Co. Croup and Pneumonia Salve.—Erie Drug Co., Erie, Pa. Composition: Essentially volatile oils (about 10 per cent) including wintergreen, camphor and menthol, in a petrolatum base. Fraudulently represented as a cure for croup, pneumonia, rheumatism, etc.—[N. J. 26736; July 1937.]

Dexter Liniment.—Chicago Drug Sales, Inc., Chicago. Composition: Chiefly phenols, essential oils including origanum and hemlock, with kerosene. Fraudulently represented as a cure for diphtheria, rheumatism, hemorrhoids, old sores, etc.—[N. J. 26735; July 1937.]

Schuh's Home Made Anti-Bilious Stomach and Liver Pills.—Chicago Drug Sales, Inc., Chicago. Composition: Extracts of plant drugs, including a laxative. For impure blood, dropsy, fevers, hemorrhoids, worms, etc. Fraudulent therapeutic claims.—[N. J. 26735; July 1937.]

Colorado Cough and Catarrh Root.—Chicago Drug Sales, Inc., Chicago. Composition: Essentially plant material, bearing evidence of insect infestation. Fraudulently represented as a remedy for asthma, catarrh, all throat, lung and stomach troubles, etc.—[N. J. 26735; July 1937.]

Palmer's Compound Carbolic Salve.—Erie Drug Co., Erie, Pa. Composition: Essentially carbolic acid, (0.7 per cent), volatile oils including menthol, and a small amount of zinc oxide, in a lanolin base. For hemorrhoids, ulcers, eczema and "all skin diseases." Fraudulent therapeutic claims.—[N. J. 26736; July 1937.]

Sterling Vapor and Rubbing Salve.—Erie Drug Co., Erie, Pa. Composition: Essentially volatile oils (about 6 per cent) including menthol, thymol and eucalyptol, in petrolatum. Fraudulently represented to be a cure for catarrh, pneumonia, hemorrhoids, etc.—[N. J. 26736; July 1937.]

Quinlax Laxative Quinine Tablets.—Erie Drug Co., Erie, Pa. Composition: In each tablet, acetanilid (0.97 grain), caffeine (0.27 grain), quinine (0.494 grain), bile salts, and an unidentified laxative drug. For la grippe, coughs, acute catarrh and bronchitis, etc. Fraudulent therapeutic claims.—[N. J. 26736; July 1937.]

Doll's (Dr.) Root and Herb Tea.—Erie Drug Co., Erie, Pa. Composition: Plant material including senna leaves, dandelion root, bearberry leaves, frangula bark, licorice root and coriander seeds. For blood, liver and kidney diseases, diabetes, Bright's disease, erysipelas, etc. Fraudulent therapeutic claims.—[N. J. 26736; July 1937.]

Solvuric Buchu and Juniper Compound Pills.—Erie Drug Co., Erie, Pa. Composition: Extracts of plant drugs including juniper and buchu, with saltpeter. Fraudulently represented as a remedy for all kidney and bladder disorders.—[N. J. 26736; July 1937.]

Sterling Compound Extract Smartweed.—Erie Drug Co., Erie, Pa. Composition: Essentially plant drug extracts, volatile oils including sassafras and mustard, with 62.5 per cent of alcohol by volume, and water. For chills, sore throat, rheumatism, colic, etc. Fraudulent therapeutic claims.—[N. J. 26736; July 1937.]

Burn Ease for Sunburn.—Erie Drug Co., Erie, Pa. Composition: Essentially volatile oils including menthol, eucalyptol, camphor and clove oil, in a base of stearic acid and water. Fraudulently represented to heal nasal catarrh, hemorrhoids, ulcers, eczema, psoriasis, etc.—[N. J. 26736; July 1937.]

Sterling Syrup White Pine and Tar.—Erie Drug Co., Erie, Pa. Composition: Essentially plant drug extracts, menthol, pine tar, chloroform, alcohol, sugar and water. For coughs, bronchial catarrh, spasmodic croup, etc. Fraudulent therapeutic claims.—[N. J. 26736; July 1937.]

Sterling Antiseptic Solution.—Erie Drug Co., Erie, Pa. Composition: Essentially boric acid, volatile oils including menthol, eucalyptol and thymol, with 27.8 per cent of alcohol by volume, and water. Falsely represented as an "antiseptic solution" and a "germ killer."—[N. J. 26736; July 1937.]

Anti-Itch.—Arnold Drug Co., Topeka, Kan. Composition: Essentially zinc oxide, petrolatum, and glycerin, with small amounts of carbolic acid, wintergreen and pink coloring. For itch, eczema and other skin disorders. Fraudulent therapeutic claims.—[N. J. 26747; July 1937.]

Bralot Rheumatic Tablets.—Bralot Laboratories, Gardnerville, Nev. Composition: Essentially 1.1 grains of aminopyrine and 4.1 grains of sodium salicylate per tablet, flavored with chocolate. Fraudulent therapeutic claims.—[N. J. 26748; July 1937.]

Bralot Laxative Tablets.—Bralot Laboratories, Gardnerville, Nev. Composition: Laxative drugs. Fraudulent therapeutic claims.—[N. J. 26748; July 1937.]

Hi-Test Catarrh Jelly.—Sam Sorbitz, Star Jobbing Co., and Continental Drug Corp., Alton, Ill. Composition: Essentially petrolatum, with small amounts of volatile oils including menthol and eucalyptol. Fraudulently represented as a cure for catarrh and hay fever.—[N. J. 26751; July 1937.]

Quality Sealed Sore Throat Remedy.—Sam Sorbitz, Star Jobbing Co., and Continental Drug Corp., Alton, Ill. Composition: Essentially water, glycerin, potassium chlorate, tannic acid and carbolic acid. Fraudulent therapeutic claims.—[N. J. 26751; July 1937.]

Lacta Kaolin Plain.—Alpha Laboratory, Inc., Chicago. Composition: Essentially sugar of milk, kaolin, agar and cocoa. Fraudulently represented as a remedy for intestinal putrefaction, etc.—[N. J. 26752; July 1937.]

Lacta Kaolin Laxative.—Alpha Laboratory, Inc., Chicago. Composition: Essentially milk sugar, kaolin, agar, cocoa and phenolphthalein. Fraudulently represented as a remedy for intestinal putrefaction, etc.—[N. J. 26752; July 1937.]

H. P. Healing Balm.—H. P. Co., Wenatchee, Wash. Composition: Essentially lead oleate and perfume, in an ointment base. Not an antiseptic or "germ killer," as represented. For hemorrhoids, all sores and infections, erysipelas, blood poisoning, sinus trouble, etc. Fraudulent therapeutic claims.—[N. J. 26753; July 1937.]

Mother Beach Stomach Tablets.—Shores Co., Cedar Rapids, Iowa. Composition: Essentially sodium carbonate (12.1 grains), bismuth subnitrate (9.2 grains), magnesium oxide (8 grains), and starch. Fraudulent therapeutic claims.—[N. J. 26754; July 1937.]

Bowman's Red Lax-Tiv.—Bowman Bros. Drug Co., Canton, Ohio. Composition: Essentially emodin-bearing drugs and aloes. For constipation, etc. Fraudulent therapeutic claims.—[N. J. 26761; July 1937.]

Nervo-Rumat Liniment.—Joe Bennett and Royal Sundries Corp., New York. Composition: Turpentine, alcohol (32 per cent by volume), water, and small amounts of camphor and insoluble material. For rheumatism, lumbago, pleurisy, etc. Fraudulent therapeutic claims.—[N. J. 26767; July 1937.]

Tam.—E. Fougere & Co., Inc., New York. Composition: Senna-leaf tissues, fig tissues and seeds, prune tissues, tissues of Carthartocarpus fruit, and starches, contaminated with mold. Adulterated in that its purity fell below the professed standard of quality claimed—namely, "100% pure natural laxative fruits," as the chief laxative ingredient was senna leaves and not laxative fruits. Fraudulent curative claims.—[N. J. 26768; July 1937.]

British Oil.—Levy Products, Inc., Tampa, Fla. Composition: Crude petroleum containing turpentine and other oils. Fraudulently represented as a relief for all scurbitic and rheumatic disorders, palsy, deafness, etc.—[N. J. 26770; July 1937.]

Olivo Hair Tonic.—Zala Perfumery Co., Philadelphia. Composition: Essentially denatured alcohol (71 per cent), an oil largely or wholly castor oil (about 19 per cent), and small amounts of glycerin, resorcinol, perfume and coloring. Fraudulently represented as a remedy for dandruff, eczema, falling hair, etc.—[N. J. 26772; July 1937.]

Olivo Hair Oil.—Zala Perfumery Co., Philadelphia. Composition: Essentially petrolatum with a fatty oil (about 2 per cent), and a small amount of resorcinol. Not a "Genuine Italian" product, as represented. For dandruff, eczema, falling hair, etc. Fraudulent therapeutic claims.—[N. J. 26772; July 1937.]

Chambers' Pills.—Chambers' Medicine Co., St. Louis. Composition: Essentially saltpeter, potassium carbonate and plant drugs including buchu, coated with chalk and green-colored sugar. Fraudulently represented as a remedy for kidney and bladder disorders, rheumatism, dropsy, etc.—[N. J. 26773; July 1937.]

Chambers' Cold Tablets.—Chambers' Medicine Co., St. Louis. Composition: Essentially acetanilid and plant drugs, including a laxative. Fraudulently represented to have "no bad effects" and to be a remedy for la grippe, coughs, fevers, etc.—[N. J. 26773; July 1937.]

Help Nature Tablets.—Chambers' Medicine Co., St. Louis. Composition: Essentially phenolphthalein and plant drugs, including a laxative. Fraudulently represented as a remedy for stomach, liver and blood disorders.—[N. J. 26773; July 1937.]

Silver Crown Hair-Scalp Tonic.—Silver Crown Remedies Co., Kingston, N. Y. Composition: Essentially water, alcohol (from 1 to 1.6 per cent by volume), quinine hydrochloride, glycerin, and small amounts of iron and sodium compounds, sulfates, perfume and color. For dandruff, falling hair, eczema, etc. Fraudulent therapeutic claims.—[N. J. 26774; July 1937.]

Okasa-Silver for Men.—Hormo Pharm G. M. B. H., Berlin, Germany. Composition: Essentially animal glandular material and plant substances, including flour and cacao. For "diseases of men." Fraudulent therapeutic claims.—[N. J. 26778; July 1937.]

Okasa-Gold for Women.—Hormo Pharm G. M. B. H., Berlin, Germany. Composition: Essentially animal glandular material and plant substances, including flour and cacao. For female disorders. Fraudulent therapeutic claims.—[N. J. 26778; July 1937.]

Sweet's Cough Balsam.—Sweet Mfg. Co., Inc., Pittsburgh. Composition: Essentially plant drug extracts including wild cherry compound, pine tar, chloroform, alcohol (5.7 per cent by volume), sugar and water. Fraudulent therapeutic claims.—[N. J. 26786; July 1937.]

Sweet's Rheumatic Remedy.—Sweet Mfg. Co., Inc., Pittsburgh. Composition: Essentially acetphenetidin (1.95 grains per tablet), potassium iodide, sodium salicylate, caffeine and extracts of plant drugs. Fraudulent therapeutic claims.—[N. J. 26786; July 1937.]

Lagreen's Famous Healing Oil (Rattlesnake Oil).—Standard Sales Co., Birmingham, Ala. Composition: Essentially kerosene and volatile oils, including mustard and sassafras. For rheumatism, colds, headache, pneumonia, etc. Fraudulent therapeutic claims.—[N. J. 26788; July 1937.]

Life-Aid.—Life-Aid Laboratory, Chicago. Composition: Essentially sulfates of sodium, magnesium and calcium, with sulfuric acid, sugar and water, and small amounts of salicylic acid, iron phosphate, saccharin and red coloring. Fraudulently represented as a remedy for indigestion, gastritis, rheumatic pains, nervousness, etc.—[N. J. 26790; July 1937.]

Colac Pile Pills.—Vasco Products, Inc., Brentwood, Md. Composition: Iron and magnesium oxides, chalk, extracts of plant drugs and a tar-like material in chocolate-coated pills. For hemorrhoids and other rectal disorders. Fraudulent therapeutic claims.—[N. J. 26793; July 1937.]

Heptuna.—Hepatin, Inc., Chicago. Composition not stated. Falsely represented as to vitamin B constituency, whereas no appreciable amount of it was present.—[N. J. 26796; July 1937.]

Juice-O-Veg.—Juice-O-Veg, Inc., New York. Composition: Water, 95 per cent, with plant juices and a negligible proportion of salts of iron, calcium, manganese, magnesium, potassium and sodium, including phosphates and silicates. Fraudulently represented to contain vitamins and to have tonic effects.—[N. J. 26801; July 1937.]

Moxon's Liniment.—Moxon Liniment Co., Mount Clemens, Mich. Composition: Essentially ammonia (not less than 7 per cent), water, alcohol, camphor and plant drug extracts. For rheumatism, dandruff, head pains, bunions, etc. Fraudulent therapeutic claims.—[N. J. 26803; July 1937.]

Indian Remedy.—Ponca Drug Co., Ponca City, Okla. Composition: Essentially epsom salt (163 grains per fluid ounce), a minute amount of iron compound, and water. Fraudulently represented as a cure for liver, kidney and stomach disorders, influenza, ague, etc.—[N. J. 26805; July 1937.]

Old Indian Liniment.—Ponca Drug Co., Ponca City, Okla. Composition: Essentially kerosene, with small amounts of mustard and eucalyptus oils, and camphor. For burns, ulcers, nervousness, rheumatism, etc. Fraudulent therapeutic claims.—[N. J. 26805; July 1937.]

Steketee's Tablets for Worms.—Hazeltime & Perkins Drug Co., Grand Rapids, Mich. Composition: Essentially saltpeter, sulfur, a laxative plant drug, and ground wormseed. Fraudulent therapeutic claims.—[N. J. 26807; July 1937.]

Steketee's Powders for Worms.—Hazeltime & Perkins Drug Co., Grand Rapids, Mich. Composition: Saltpeter, sulfur, phenolphthalein and wormseed. Fraudulent therapeutic claims.—[N. J. 26807; July 1937.]

Wonder Health Water.—Wonder Health Water Co., Hot Springs, Ark. Composition: "A lightly mineralized, slightly alkaline mineral water of approximately the same composition of numerous city water supplies throughout the country." Fraudulently represented as having medicinal effects.—[N. J. 26809; July 1937.]

Nox-A-Boil.—Nox-A-Boil Laboratories, White Pigeon, Mich. Composition: Essentially iron, calcium and magnesium compounds including carbonates, phosphates, sulfates and chlorides, and talc, sugar, starch and a fatty material. Fraudulently represented as a cure for boils, carbuncles, tonsillitis, abscesses, ulcerated teeth, etc.—[N. J. 26811; July 1937.]

Antiseptol.—Giustino Sallusto Co., New York. Composition: Essentially boric acid, zinc sulfate and menthol. Bacteriologic tests showed it was not antiseptic when used as directed. Fraudulently represented as a disinfectant and antiseptic when used as a vaginal douche, "disinfecting the female sexual organs . . ."—[N. J. 26812; July 1937.]

Lane's Pills.—Charles E. Lane & Co., St. Louis. Composition: Essentially calomel, a laxative plant drug, sugar, and small amounts of ferrous carbonate and strychnine. For stomach and liver disorders, excesses, etc. Fraudulent therapeutic claims.—[N. J. 26813; July 1937.]

Stewart's (Dr. Mary E.) Antiseptic Powder.—American Pharmaceutical Co., Inc., New York. Composition: Essentially boric acid, zinc sulfate, flavored with eucalyptol and wintergreen. Not antiseptic when used as directed. Fraudulently represented as a remedy for various vaginal disorders.—[N. J. 26814; July 1937.]

Lane's Tea.—Kemp & Lane, Inc., LeRoy, N. Y. Composition: Claimed to consist of senna, anise seed, fennel seed, licorice root, elecampane root and coriander seed. Specimen was reported infested with insects. Fraudulently represented as a remedy for "faulty intestinal elimination."—[N. J. 26816; July 1937.]

Vacher-Balm.—James F. Stras, LaCrosse, Wis. Composition: Essentially menthol, oil of eucalyptus and petrolatum. For catarrh, croup, etc. Fraudulent curative claims.—[N. J. 26820; July 1937.]

Bol Lecznik Liniment.—Reliable Merchandise Co., Chicago. Composition: Alcohol (60.8 per cent), chloroform (4.6 minims per fluidounce), ether, ammonia, red pepper, water and volatile oils such as peppermint and mustard. Misbranded because the proportions of alcohol, ether and chloroform were not declared, and because of fraudulent therapeutic claims.—[N. J. 26825; July 1937.]

Musterdone.—Reliable Merchandise Co., Chicago. Composition: Camphor, menthol, salicylic acid, wintergreen oil and volatile mustard oil, in petrolatum. Fraudulently represented as a remedy for sore throat, tonsillitis, neuralgia, rheumatism, etc.—[N. J. 26825; July 1937.]

Universal Kidney, Liver and Stomach Tea.—Reliable Merchandise Co., Chicago. Composition: Dried herbs and seeds including anise, lavender and senna. Fraudulent therapeutic claims.—[N. J. 26825; July 1937.]

Universal Stomach Drops.—Reliable Merchandise Co., Chicago. Composition: Alcohol, water, glycerin, red pepper, a laxative plant drug and peppermint oil. Fraudulent therapeutic claims.—[N. J. 26825; July 1937.]

Universal White Pine Cough Balsam.—Reliable Merchandise Co., Chicago. Composition: Pine tar, salicylic acid, resinous material, alcohol and water. Fraudulent therapeutic claims.—[N. J. 26825; July 1937.]

Mase Zywokostowa Ucco Salve.—Reliable Merchandise Co., Chicago. Composition: Menthol, camphor, eucalyptol, oil of wintergreen and salicylic acid, in petrolatum. For tonsillitis, neuralgia, rheumatism, stiff neck, etc. Fraudulent therapeutic claims.—[N. J. 26825; July 1937.]

Correspondence

SPREAD OF THE VIRUS OF POLIOMYELITIS

To the Editor:—In a recent issue of THE JOURNAL (August 13, p. 605) Sabin reported that poliomyelitis was produced when he injected the virus in the tonsillopharyngeal area of *Macacus rhesus* monkeys. He indicated that after tonsillopharyngeal injection the virus probably progressed along peripheral nerves to the bulbar nuclei, thereby producing bulbar palsy.

That virus can spread along nerves of the upper part of the gastrointestinal tract to the medullary area has been demonstrated in our laboratory. How bulbar palsy might develop in the human being has been previously discussed (Toomey, J. A.: Poliomyelitis, *Am. J. Dis. Child.* 50:1362 [Dec.] 1935). The possible pathways of infection from the gastrointestinal tract, including the one from the glossopharyngeal area, were outlined in a recent publication (Toomey, J. A.: Round Table Discussion on Poliomyelitis, *J. Pediat.* 7:279 [Aug.] 1935, fig. 1). When the isolated seventh nerve (Toomey, J. A.: The Seventh Nerve as a Possible Pathway for the Transmission of the Virus of Poliomyelitis, *Am. J. Dis. Child* 51:58 [Jan.] 1936), the taste buds of the tongue (*id.*, *ibid.*) or the vagus nerve itself was injected (Toomey, J. A.: Experimental Production of Bulbar Poliomyelitis, *Proc. Soc. Exper. Biol. & Med.* 32:628 [Jan.] 1935) a distinct type of bulbar poliomyelitis occurred. Five of the eight *Macacus rhesus* monkeys which were given vagal injections developed the disease; four of the five had a bulbar type of paralysis, and the symptoms in four came on in from three to six days after injection. The disease was produced earlier than when the virus was injected intracerebrally.

After operation about the oral cavity, as elsewhere, there are new vessels, new gray nerve fibers and cut nerve ends, so that the natural chances for absorption of the virus should be increased; therefore the possible dangers of operations about the oral cavity during seasons when there is a high incidence of poliomyelitis is properly emphasized.

JOHN A. TOOMEY, M.D., Cleveland.

MODE OF ACTION OF INSULIN IN SCHIZOPHRENIA

To the Editor:—Neither Dr. Ernst Gellhorn's original article nor Dr. Friedman's communication add much light to the seeming puzzle of the action of insulin on the nervous system in schizophrenia. Their confusion arises from the indiscriminate mashing of chemical and physical evidence with what Dr. Kettering would call too much meaningless scientific verbiage.

The faculties of the mind are discernible only through biochemical reactions expressed or observed in terms of physical activity or inaction. Consequently the psyche—from the standpoint of natural science—is elutable only through an understanding of its dependent physical phenomena—electrical, chemical, physical—which are subject to equivalent translation, since they are merely aspects of a unitary process. Brain wave recordings, lie detections, chronaxias, electrocardiograms are the electrical "shadows," as heat and size (growth, decay, atrophy) are the physical reflection of matter—organic and inorganic chemicals—ionized and in motion in solution.

Physiologic activity is accompanied by the production of organic acids for whose adequate neutralization by the way of catabolism dextrose is essential. Dextrose is necessary in the normal respiration or metabolism of tissues. It is accumulated, stored, fixed, condensed or polymerized as glycogen in the tissues for this purpose in states or conditions of relative

inactivity (rest). The same result is obtained medically by the application of the chemical principle of increasing the concentration of the substances which force the reaction in the opposite direction. This is done by the administration of insulin with dextrose, for though we speak much of the treatment of schizophrenia with insulin it must not be overlooked that it is an accompaniment of dextrose therapy, more likely than not in a saline medium which also is no inconsiderable factor.

Our psychiatrists have suddenly found themselves possessed of a method of treatment which, though psychic in its effects, is not "psychic" in the intent of its application. And much as they emphasize the need of "expert skill" in its application there is reason to fear that they are no more competent in its use than is an intern in the treatment of diabetes mellitus, for shock is not an essential feature but, rather, a complication to be avoided. Since the effectiveness of the measures is dependent on the principles that obtain in the care of diabetic patients under insulin there can be no more reason to look on the development of shock less fearfully than does the internist in the care of persons with diabetes.

JOHN F. QUINLAN, M.D., San Francisco.

PROTEIN RESTRICTION IN NEPHRITIS

To the Editor:—According to current concepts of renal physiology, the end products of protein metabolism are excreted into the urine without any effort on the part of the kidney. That is to say, urea, sulfate and phosphate, along with most of the other constituents of the urine, pass the glomerular capsule by the physical process of filtration, energy being supplied by the heart. The work of the kidneys is carried on by the renal tubules; it is chiefly concerned with resorption from the glomerular filtrate of water, dextrose and physiologic salts which must be retained by the body. This work is rather constant and independent of the diet.

Nevertheless, as brought out in the recent paper of Drs. Murphy and Rastetter discussed by Dr. Addis (THE JOURNAL, August 20, p. 668), restriction of protein in nephritis continues to be practiced with a view toward putting the kidneys at rest.

Aside from theoretical considerations, clinical evidence also offers little support for the practice of protein restriction. The work of Keutman and McCann was mentioned in the paper. They found that a high protein diet in acute nephritis neither retards recovery nor aggravates hematuria.

We are just a trifle slow in getting our medical practice on a physiologic basis.

A. P. BRIGGS, M.D., Augusta, Ga.

"CONTRAINDICATED BACTERIOPHAGE THERAPY"

To the Editor:—In reference to the editorial comment "Contraindicated Bacteriophage Therapy" (THE JOURNAL, August 6) I am glad to find this problem brought to the attention of the medical profession.

In my hands, bacteriophage therapy has frequently been distinctly beneficial against staphylococcal infections when used locally. I have had little experience with antistreptococcal bacteriophages because of their extreme specificity. For each case, however, bacteriophage was not employed until it had been developed on the particular infecting organism and had reached a high level of efficiency (at least 1×10^{-7} by serial dilution) against it. This was achieved by a process of repeated contacts and filtrations (Goldsmith, N. R.: A Procedure for the Preparation of Autogenous Bacteriophage for Therapy, in *Clinical Laboratory Methods and Diagnosis*, St. Louis, C. V. Mosby Company, 1935, pp. 770-771).

Further, frequent tests were made of the effectiveness of the bacteriophage against later cultures from the lesion, and whenever the resistance of the organism had increased new batches of bacteriophage were prepared against the latest culture. This all entails considerable work, but is, I believe, probably the only way at present to use bacteriophage safely and effectively. I hence feel that stock or commercial bacteriophage preparations, no matter how potent against any or several strains of bacteria when prepared and ampuled, are relatively worthless when used for a specific case.

NORMAN R. GOLDSMITH, M.D., Pittsburgh.

DEATHS FROM TYPHOID IN MIAMI

To the Editor:—Through an unfortunate statistical error, which should have been detected by me, you were advised that the number of typhoid deaths in Miami in 1937 was eight. The actual number was six. Two of these were of nonresidents, ill on arrival, having contracted their sickness before entering Florida. On the basis used last year (127,600 population), the first figure gave the rate per hundred thousand of population of 6.3, as used in the article appearing in the July 30 issue of THE JOURNAL. When 6, the correct figure, is used, the rate is 4.7. This year's rates will be based on an estimated resident population of 140,000, of which 110,000 are white persons and 30,000 Negroes.

GEORGE N. MACDONELL, M.D., Miami, Fla.

Director of Public Health.

TRAUMA AND APPENDICITIS

To the Editor:—In reply to Dr. Royal H. Fowler (THE JOURNAL, July 30, p. 466) and to add to the voluminous literature on this subject I will report this case:

A farmer lad aged 21 with absolutely no history of gastrointestinal trouble, was kicked by a cow, while milking. The blow was an indirect one, as the rim of the pail was forcibly driven across the region of the umbilicus and right lower quadrant. Immediately after the trauma he suffered abdominal pain, felt weak and nauseated and was unable to eat. For the next six days, anorexia was present with abdominal pain referable to the middle and right lower quadrant. Nausea was present but he had not vomited. His parents brought him to my office after the end of the sixth day. He appeared pale and very ill. A cursory examination of the abdomen revealed a mass the size of an orange in the right lower quadrant. Clinically I thought it was a hematoma but on taking his temperature, which was 101, a blood count was done. This revealed 4,400,000 erythrocytes, 21,000 leukocytes, 75 per cent hemoglobin, 76 per cent polymorphonuclears and 24 per cent lymphocytes.

A diagnosis of appendical abscess was made and a completely disintegrated retrocecal appendix with abscess formation was found at operation. Rubber tissue drains were inserted into the abscess cavity, the suprapubic pouch and up the lumbar gutter to the liver bed. Recovery after six weeks of drainage was complete.

I am unable to offer any other explanation but that the contents of the cecum were forcibly squeezed into the appendix with subsequent traumatic rupture. The clinical course checks perfectly.

After all, from a medicolegal standpoint the appendix always is supplied with colon bacilli and any agent dispersing it in the peritoneal cavity is the active traumatic cause. Outside of previous disease and even in the presence of previous disease, many industrial commissions hold that the disabling trauma is responsible for the breakdown of the part involved. At least the report of this case may bring forth more data, pro and con.

RONALD B. ROGERS, M.D., Neenah, Wis.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

FACE INFECTIONS AND INTRACRANIAL COMPLICATIONS

To the Editor:—By what routes may pyogenic infections of the upper lip and vestibule of the nose cause fatal intracranial complications? What are the common serious complications which may occur with pyogenic infections involving the upper lip and vestibule of the nose? Can you supply any references in the literature or recent textbooks dealing with infections in these regions?

M.D., Ohio.

ANSWER.—The most direct route is from the nose and extends along the anterior and posterior ethmoid veins to the superior ophthalmic vein, which opens into the cavernous sinus without valves. The most frequent direct route from the upper lip and the next most direct one from the nose to the cavernous sinus extends along the external, the labial and the nasal veins to the anterior facial, the angular, the nasofrontal and the superior ophthalmic vein.

Another direct but less frequent route of infection is from the nasal and labial veins to the perforating branches of the anterior facial which anastomose with the inferior ophthalmic vein. This partly empties directly into the cavernous sinus and sends branches to the superior ophthalmic and others to the pterygoid venous plexus. Infection may extend from the nose or lip to the pterygoid plexus along either anastomosing branches from the anterior and posterior ethmoid veins or anastomosing branches to the plexus from the sphenoparietal veins. Extension of infection from the pterygoid venous plexus to the cavernous sinus may spread along collateral veins, passing through the foramen ovale, the foramen lacerum, or more indirectly along anastomosing branches to the middle meningeal vein and other collaterals to the sphenoparietal sinus and to the cavernous sinus. Infection may extend indirectly along the anterior facial vein and its branches to the supra-orbital or frontal veins, which anastomose with the diploic veins. These anastomose with local branches to the cavernous sinus and also with branches leading to the sphenoparietal sinus, which sends collaterals to the cavernous sinus.

Unfortunately the most direct route from the nose is along the anterior and posterior ethmoid veins to the superior ophthalmic vein, all of which are inaccessible for ligation. The deep perforating branches of the anterior facial vein to the inferior ophthalmic vein also are inaccessible. Clairmont (quoted by Christopher, Frederick: *Minor Surgery*, ed. 3, Philadelphia, W. B. Saunders Company, 1936) has advocated both proximal and distal ligation of veins in furuncles of the face. These veins should be double ligated and completely cut across.

The more frequent serious complications are spreading thrombophlebitis along the veins to the cavernous sinus or to the sphenoparietal sinus with thrombosis, suppuration and meningitis; septicemia, and pyemia with metastases to various viscera. All infections on the anterior part of the face and especially on the upper lip and nose should be treated conservatively by absolute rest to the facial muscles, warm compresses, avoidance of early incisions and prevention of trauma. Ligation of veins, especially of the angular vein, to check a spreading infection may be life saving but must be done early. Incisions are contraindicated in the early stages, but occasionally incisions for evacuation of pus may be necessary in the later stages of suppuration but should be done by an experienced surgeon. Systemic treatment and specific medication or local treatment may be of value depending on the etiology, the course and stage of infection, and the existence of complications or associated diseases.

PITUITARY AND SCOPOLAMINE IN LABOR

To the Editor:—Can you tell me whether J. P. McEvoy, author of the article "Our Streamline Baby" in the *Reader's Digest* for May 1938, is a physician? I have been using pentobarbital sodium (nembutal) for over a year quite successfully in many cases. Can you give an opinion as to the advisability of administering solution of posterior pituitary and scopolamine in all primiparas? What is your reaction to this article? Do you consider it authentic for publication in medical journals? Patients react differently to these agents and I feel that it is not as uniformly successful as this article would indicate. Will you please enlighten me as to the current opinion of leading obstetricians regarding the combination as outlined in this article?

CHARLES A. COFFIN, M.D., Kewanee, Ill.

ANSWER.—J. P. McEvoy is not a physician but a well known humorist and writer.

It is not possible with complete safety to use either solution of posterior pituitary or scopolamine as a routine in all primiparas although scopolamine has been used a great deal and is one of the least dangerous of amnesics. Solution of posterior pituitary is a dangerous remedy and, even when given in minute doses, can produce rupture of the uterus and death of the fetus in susceptible patients. In toxemias it may cause convulsions. There should be a positive scientific indication for every dose of these remedies administered.

Whenever a doctor sets a day for the labor and starts it either with rupturing the bag of waters or the administration of solution of posterior pituitary he assumes considerable responsibility, first, because it is not known when normal pregnancy terminates, and whether the child, even though large enough, is endowed with sufficient vitality to live outside the uterus, and, second, because certain complications such as prolapse of the cord and tumultuous uterine action can occur. If he adds to this a narcotic, the risks are augmented because, among other reasons, the necessity for operative intervention is increased.

The woman must pay for the relief from the pain of labor, and perhaps also the baby. Recent studies by Courville, Schreiber and Gates show that anoxia of the brain leaves permanent damage in its structure, and the babies are often anoxicemic during labor and for hours afterward.

LARGE PERFORATION OF NASAL SEPTUM

To the Editor:—A patient has a large perforation of the nasal septum (postoperative). Can you suggest what substance would be most suitable for an artificial septum, so that the patient can remove, clean and replace it?

LOUIS SCHWARTZ, M.D., New York.

ANSWER.—Since the perforation is a large one it would obviously be impossible for the patient to pass a prosthesis through the nares that would be large enough to close the hole. Neither would it be possible for such a prosthesis to remain accurately in situ even assuming that the patient was able to introduce it. Finally, even if such an object were accurately placed within the nose it would soon cause so much irritation as to necessitate its early removal. The use of foreign materials within the nasal cavity in contact with mucous membrane is extremely unpractical and has never proved successful. If the perforation is too large to be closed by the usual plastic procedures, it is best left alone. The only inconvenience resulting would be a tendency to crusting and possibly bleeding when the crusts are expelled. To overcome this difficulty the patient may use a mixture of boric acid 5 per cent in equal parts of hydrous wool fat and petrolatum pushed into the nose two or three times daily. Also the occasional application of scarlet red emulsion (scarlet red sulfonate N. N. R. 4 per cent) to the margins of the perforation will help to prevent scabbing.

METRONOSCOPE AND OPHTHALMOGRAPH

To the Editor:—I should like information on the value of the metronoscope and ophthalmograph, manufactured by the American Optical Company.

M.D., Iowa.

ANSWER.—The ophthalmograph is an instrument for photographing the eye movements during reading. It is claimed that many cases of reading disability due to poorly coordinated ocular movements may be detected by this instrument and corrected by exercises in rhythmic reading given by the metronoscope. Experience with the ophthalmograph proves that good pictures of the ocular movements can be obtained with it, but some skill and experience are required to use it. It is chiefly of value in clinics for special education and not, it is believed, designed for clinical ophthalmologists. Exercises with the metronoscope should probably be used only when indicated by results of tests with the ophthalmograph. It is not an instrument particularly well adapted for orthoptic training in ordinary cases of muscle imbalance.

TRICHOMONAS URETHRITIS IN MALE

To the Editor:—A patient claims that several physicians have diagnosed his urethritis, with which he has been bothered for two years, as being caused by the trichomonas parasite. It is the same parasite that causes trichomonas vaginalis in women. I should like a discussion of this condition in males. What is the treatment?

L. D. LEBOLD, M.D., Warsaw, Ohio.

ANSWER.—Trichomonas urethritis in the male is relatively rare, as judged by the number of recorded cases, but there are probably many cases of "nonspecific" urethritis in which the diagnosis is missed. The organism may be present in either the anterior urethra or the prostatic secretion or both. The symptoms are a urethral discharge, which is generally mucoid at first and later purulent, burning and frequency, and itching along the ventral surface of the penis. The wife of the patient is frequently found to be harboring the organism. Diagnosis is based on microscopic identification of the trichomonad in the fresh smear from the urethra, expressed prostatic secretion or centrifuged urine.

Treatment is by injection of 0.25 per cent silver nitrate solution into both the prostatic and anterior urethra to be retained for three minutes. The injections may be given every other day and may be alternated with a 1:1,000 solution of acriflavine.

If possible, the sexual contacts of the patient should be investigated as a source of infection, especially if there are recurrences.

CHAULMOOGRA OIL IN ARTHRITIS

To the Editor:—An article by Dr. Irving S. Cutter published recently in a newspaper claimed 54 per cent cures in a series of patients treated for chronic arthritis with weekly injections of chaulmoogra oil. I should like to know more about this method of treatment.

VIRGIL GORDON, M.D., Sealy, Texas.

To the Editor:—What information can you give me on chaulmoogra oil in the treatment of arthritis? How is it used and where can it be procured?

HERBERT R. SUGG, M.D., Clinton, Iowa.

ANSWER.—In 1931 McIlhenny expressed the belief that the use of chaulmoogra oil in the treatment of leprosy might be responsible for the rarity with which "secondary infectious arthritis" occurred in lepers. He therefore gave to patients with atrophic, hypertrophic or mixed arthritis intramuscular injections of the crude oil biweekly and enteric capsules of the oil by mouth daily. McIlhenny's results, as noted in his "preliminary report" (*New Orleans M. & S. J.* 84:182 [Sept.] 1931), were as follows: Of thirty-nine patients so treated, "without exception every patient has shown improvement; many complete relief of symptoms and restoration of function; others arrestment of the disease and reduction of deformities." Improvement was to be expected during the second week of the treatment, and the "average patient" become symptom free in about eight weeks. Brief case reports of only five of the thirty-nine cases were given. In a few cases sterile abscesses developed when the oil was inadvertently injected into fascial planes or periosteum.

The results were equally good in hypertrophic and in the mixed type of arthritis. This observation is of itself sufficient reason to cast doubt on the claim that chaulmoogra oil might be a specific therapy for rheumatoid arthritis, because rheumatoid and hypertrophic arthritis are generally quite distinct.

In 1933 Hebert also published a "preliminary report" (*Tri-State M. J.* 5:1050 [Feb.] 1933). Chaulmoogra oil was given by injection and orally to twenty-one patients with arthritis, generally of the atrophic type; seventeen patients noted improvement of varying degrees. By intramuscular injections Robinson (*Tri-State M. J.* 9:1838 [May] 1937) treated "approximately two hundred cases" generally of the atrophic and secondary infectious (including gonorrheal) types. A mild, febrile reaction resembling that which follows injection of foreign protein generally was induced. Results were not tabulated and notes on only four cases were given. Best results were reported to have been obtained in cases of acute infectious (gonorrheal) arthritis and acute atrophic arthritis. In cases of subacute and chronic atrophic arthritis some analgesia and increased articular motion were provided. Little or no relief was obtained by patients who had advanced atrophic arthritis, hypertrophic arthritis or "mixed" arthritis. Collections of unabsorbed oil had to be removed by aspiration in nine cases and abscesses were drained surgically in two cases.

Forestier and Certonciny (*Gaz. med. de France* 44:911 [Nov. 1] 1937) and more recently Smith, Blocker and Turner (*J. Florida M. A.* 24:586 [May] 1938) have reported their results. The results of Smith and his colleagues in sixty-five cases were as follows: Of fifteen patients who had atrophic arthritis, thirteen became symptom free; of thirty-three patients

who had mixed arthritis, eighteen became symptom free; little or no beneficial effect was obtained by seventeen patients who had hypertrophic arthritis.

In general, proponents of this therapy have failed to analyze their results critically and, from the meager data given, the reader has been unable to form an independent opinion. The length of time these patients have been studied is too short to justify a final opinion on the value of this remedy. The results of the injections are similar to those which long have been obtained from more orthodox measures, especially intramuscular injections of such foreign proteins as milk and intravenous injections of triple typhoid vaccines. Untoward results are rare following the use of these foreign proteins, apparently being not as frequent as the incidence of sterile abscesses after injections of chaulmoogra oil. It is probable that the beneficial effects of injections of the oil result from the mild reaction, resembling that to foreign protein, which is induced. It seems suggestive that although seven and five years have elapsed since the publication of their "preliminary results," neither McIlhenny nor Hebert have reported further. As each of them noted, for chronic arthritis there have been more cures discovered than for any other disease but most of them have been discarded. It remains to be seen whether chaulmoogra oil therapy of chronic arthritis will eventually meet a similar fate.

It is administered intramuscularly in doses of from 3 to 5 cc. or orally in enteric coated capsules in doses of from 0.3 to 1.6 cc. The intramuscular method of administration has been preferred by most workers. Occasionally abscess formation is encountered. The drug can be obtained from any of the large pharmaceutical companies.

INTRACTABLE BRONCHIAL ASTHMA

To the Editor:—A woman aged 21 has had asthma since the age of 9. Until about five years ago her attacks were mild and were relieved by ephedrine capsules. Since then the attacks have become worse and hypodermic administrations of epinephrine have been required to relieve her. About four months ago she was overcome by a severe attack, and it was discovered within a short time that she had become epinephrine fast. Epinephrine not only failed to relieve her but it affected the heart, and after the injection she became weak and faint with severe headache. Aminophylline $7\frac{1}{2}$ grains (0.5 Gm.) intramuscularly was given, effecting relief when the attack was severe. This severe attack lasted for about a month. Since then she has still been wheezing slightly and is overcome by severe paroxysms of coughing with a slight amount of expectoration. After the paroxysmal cough, which lasts sometimes from three to five minutes, wheezing and choking is so severe that slight cyanosis at times develops. This is quickly relieved by the oral inhalation of epinephrine chloride 1:100. After this she wheezes only slightly and is quite comfortable until another attack of coughing. When one listens to her chest, there is evidence of bronchial constriction and a large amount of secretion. She does not have a temperature above normal at present. Two months ago she had a temperature of 103 F. and I was afraid she would get pneumonia. Dzsinič (*Klin. Wchnschr.* 14: 1612 [Nov. 9] 1935) discussed the treatment of asthma and urticaria with histamine. There are manufacturing pharmacists who have histamine phosphate 1:1,000 on the market which they recommend for the treatment of asthma. Their plan of treatment is as follows: first injection, 0.05 cc. intracutaneously; next eleven injections, all hypodermically, 0.1 cc., 0.2 cc., 0.3 cc., 0.5 cc., 0.75 cc., 1 cc., 3 cc., 5 cc., 7 cc., 8 cc., 9 cc., respectively; thirteenth to twentieth injections, 10 cc., hypodermically. What is your opinion as to the use of these preparations? Would you suggest that the treatment be used in this case? Small doses may be all right but the larger doses might be harmful. A continuous attack of asthma for four months is beginning to affect her general system.

M.D., Nebraska.

ANSWER.—The symptoms given are typical of those found in what is known as chronic intractable bronchial asthma ("chronic asthma" or "status asthmaticus"). Histamine has been used in such cases with varying results.

Gotsch (*Ztschr. f. klin. Med.* 129:593, 1936) tested the reactions to a weak galvanic current and to histamine on forty-five allergic and eighty-two nonallergic persons; he found no relationship between histamine hypersensitivity and allergy or between allergic reactions and the skin reaction to electrical stimulations. He gave histamine transcutaneously by means of a galvanic current of 8 milliamperes; a series of treatments was given. Twenty-one of thirty patients with bronchial asthma were entirely or partially relieved.

Dzsinič (*Klin. Wchnschr.* 14:1612 [Nov. 9] 1935) believes that in asthma histamine is liberated from the vascular cells of the bronchi and then produces the local and general symptoms of asthma. By introducing exogenously small doses of histamine, one may desensitize allergic persons against the histamine, formed within the system, according to the author. He treated fifteen cases of bronchial asthma with "complete cure" in twelve; the remission has lasted fifteen months. Some patients could tolerate only small doses.

There seems little doubt that histamine or a histamine-like substance is responsible for various allergic manifestations, including bronchial asthma. The use of histaminase, an enzyme supposed to destroy histamine, would seem more logical than the administration of histamine itself. So far, however, the use of histaminase is purely experimental and no clinical results have been reported. If used, histamine should be given cautiously.

Aminophylline intravenously in doses of from 0.24 to 4.48 Gm. diluted to 10 cc. with physiologic solution of sodium chloride has given excellent results in severe cases of bronchial asthma in which the patients were epinephrine fast, according to Herrmann and Aynesworth (*J. Lab. & Clin. Med.* 23:135 [Nov.] 1937). Greene, Paul and Teller (*THE JOURNAL*, Nov. 20, 1937, p. 1712) likewise obtained symptomatic relief with this drug.

Other methods of treatment have also been advocated in "status asthmaticus"; e. g., roengen treatment, large doses of stock or autogenous vaccine, bronchoscopic aspirations, instillations, of iodized oil and intravenous injections of typhoid vaccine. It is noteworthy that some patients in whom epinephrine fails can obtain satisfactory relief if the drug is injected in different locations each time. In desperate cases epinephrine may be injected intravenously, often with dramatic results.

IRRADIATION OF PITUITARY

To the Editor:—When x-rays are used to reduce the size and activity of the posterior pituitary, how long does such reduction last? Is it in any degree permanent?

RAY H. FISHER, M.D., Oakland, Calif.

ANSWER.—The literature makes scant mention of the use of x-rays to reduce the size and activity of the posterior lobe of the pituitary. Harrison (*A Textbook of Roentgenology*, Baltimore, William Wood & Co., 1936, p. 215) says that "when hyperplasia is present, the effect of irradiation upon the posterior lobe is greater than on the anterior, though both show definite response, the clinical results giving the impression that the cells, both chromophobe and chromophil, are very radiosensitive during their stage of hyperplasia." Irradiation directed at the posterior lobe would probably strike the anterior lobe with equal intensity. Eosinophilic and basophilic adenomas of the anterior lobe are quite sensitive to x-rays. Irradiation of these tumors is frequently followed by relief of symptoms and their growth appears to be stopped, at least for a period of several years.

Overactivity of the posterior lobe is thought by some to be responsible for eclamptic states, essential hypertension and the nephropathy of pregnancy. While a large mass of evidence is offered in support of this belief, probably the majority of workers regard it as inadequate. There is apparently no record of irradiation of the pituitary having been done as a treatment for eclampsia and allied conditions in pregnancy. Irradiation of the pituitary and adrenals has been practiced in the treatment of essential hypertension and diabetes mellitus. A considerable percentage of patients are reported as improved after treatment (Culpepper, W. L.; Madden, E. E.; Olson, E. C., and Hutton, J. H.: *Endocrinology* 22:236 [Feb.] 1938), but such improvement is usually not permanent. Further irradiation appears to be required at varying intervals of time. Such treatments, however, are not directed solely at the posterior lobe; neighboring structures are irradiated at the same time.

PHENOLPHTHALEIN TEST FOR GASTRO-INTESTINAL ULCERATION.

To the Editor:—What is the technic for the phenolphthalein test for ulceration of the gastrointestinal tract?

M.D., Cuba.

ANSWER.—The phenolphthalein test for ulceration of the gastrointestinal tract, as described by Dr. Edward E. Woldman in the *American Journal of Digestive Diseases* (5:221 [June] 1938), consists of the administration of 10 cc. of a 1 per cent solution of phenolphthalein in 95 per cent alcohol. The 10 cc. of the phenolphthalein is diluted to 30 cc. at the time that the phenolphthalein is given. This solution should be administered in the morning when the patient is in the fasting state because food may prevent the solution from reaching the lesion in the gastrointestinal mucosa. The patient is instructed not to eat or drink for one hour after taking the phenolphthalein. Specimens of urine are obtained in two and four hours afterward, and if the patient has some condition which may delay the

appearance of the drug, such as acute or chronic nephritis, cardiac failure, fever or dehydration, a six hour specimen may be desirable.

A portion of each specimen of urine is poured into two containers, one to be used for comparison of color with the other portion, to which 10 per cent sodium hydroxide solution is added. The best containers for the specimens are white porcelain evaporating dishes or small beakers placed on white paper. Test tubes are not satisfactory for these color comparisons, for there is not enough depth in the fluid in them to bring out the color. The 10 per cent solution of sodium hydroxide is added with a dropper until no more change in color takes place. Occasionally a precipitate is formed when the alkali is added because of the presence of earthy phosphates which are insoluble in alkaline solution. The urine must be examined promptly, for otherwise false positives may be obtained. The test should not be repeated for several days, as phenolphthalein can be detected in some instances for from forty-eight to seventy-two hours after ingestion.

If the test is positive for free phenolphthalein in the freshly passed urine, as described, a break in the mucous membrane of the gastrointestinal tract is indicated. If the test is negative, the mucous membrane is thought to be intact. In a series of 112 cases, Woldman found the error to be less than 3 per cent, both for positive and for negative results. The reliability of the test depends on the small quantity of phenolphthalein used and prompt examination of the urine.

INHERITANCE OF ALBINISM AND MENTAL RETARDATION

To the Editor:—Can you give me some light on the transmissibility of albinism? The specific case is that of a young man whose sister is an incomplete albino. If he married a normal girl in whose family there was no known case of albinism, what would be the likelihood of this defect appearing in the descendants? The sister constitutes the only known case in his family history. There is another factor in that a younger brother shows delayed mental development. At the age of 12 he has completed the work of the fifth grade. He was 3 years old before he could talk intelligently. Apparently it is a matter of retardation rather than deficiency. There are no other mental troubles in the family history. What advice can I give this young man about the advisability of marrying?

M.D., Washington.

ANSWER.—Albinism and partial albinism are inherited as recessive traits. A person with normal coloring could carry the gene or genes for albinism. If he married a woman of normal coloring who chanced also to be a carrier, some albino children might result. But if there is no history of albinism in the ancestry of such a woman there would be no possibility of albinic offspring from this mating.

No definite answer can be given to the second part of the question. One would need to have the retarded child examined by experts to determine whether he is a true mental defective. If he were, the condition might be due to birth injury or infantile disease and therefore would not be hereditary. Even if a hereditary defect, however, the trait would be recessive and accordingly transmissible in a manner similar to albinism.

"TEBIGEN" TUBERCULIN TEST

To the Editor:—The enclosed pamphlet was received from Ernst Bischoff Company concerning their new product, "Tebigen." Accompanying it was a two page list of patients who had been tested by the Gruskin intradermal test for tuberculosis. These tests were conducted at Temple University Hospital. All the patients who gave a positive result to the test were found to have x-ray evidence of tuberculosis, bone tuberculosis or positive sputum. Those who gave a negative reaction showed evidence of healed tuberculosis or at least no evidence of active tuberculosis was found. What do you know about this test?

M.D., Illinois.

ANSWER.—The only printed literature on Tebigen is that distributed by the manufacturers themselves. The circular of the manufacturers, Ernst Bischoff & Co., Ivoryton, Conn., labels the product Dr. Gruskin's Homologous Antigen for the Diagnosis of Tuberculosis and states that it "differs from all previous agents employed for this purpose in that it is not prepared from the tubercle bacillus but from a protein fraction of the fibrin of a tuberculous animal." The method of manufacture is briefly described in the circular, and instructions are given for the performance of the test. The statement is made that reactions are given only in patients with active tuberculosis, and that the test distinguishes human type from bovine type infection.

Dr. Gruskin has published no articles on this subject himself, except a brief preliminary notice entitled "An Intradermal Test

for Tuberculosis," which appeared a year ago in the *Skull*, a magazine published by the School of Medicine of Temple University (pp. 306-307, 1937). The designation Tebigen is not used in this paper. In the brief article in the *Skull* a test is described "based on the principle that in tuberculosis a characteristic protein is developed which is absent if the process is eliminated." The material used in the intradermal test is stated to be essentially a neutralized alkaline extract of the washed fibrin from the blood of tuberculous guinea pigs. The statement is made that following the intradermal injection of a suitable amount of the extract pseudopodia will appear around the injection wheal in a few minutes in positive cases, i. e., cases of clinically active disease, whereas in arrested cases, still positive to the usual tuberculin tests, no such reaction occurs. The negative response in the latter cases is believed to represent immunity.

In the absence of any detailed scientific reports on the test, it would seem inadvisable to use it.

SUGAR AND SALT IN LIVER CIRRHOSIS

To the Editor:—An article by Dr. Logan Clendening published in a St. Louis paper June 6 treats of reconditioning a damaged liver. He recommends feeding sugar and simple sweets and says that salt is also a valuable food to assist the liver to regenerate. He said that several years ago Dr. Rowntree advocated salt and sugar for cirrhosis and believed that considerable regeneration occurred. For nearly a month I have had under treatment a sedentary man of 57 whose liver was enlarged five fingerbreadths and its firm, round edge protruded. He weighed 245 pounds (111 Kg.) and was 5 feet 10 inches (178 cm.) tall. His complexion was rough and deep red, his palms were deep red (is this characteristic of liver troubles?), there were no varicosities on the trunk, the heart was normal in size and tones, and there was moderate edema to the midleg. His blood pressure was 155 systolic, 70 diastolic. The urine and reflexes were normal. He had drunk an average of a pint of whisky daily for five years. There were moderate neuritic symptoms. The patient has been in the hospital on a low carbohydrate, low fat diet. He has had daily fomentations to the liver and 21 meter diathermy by either the pancake coil or condensation pads (which is better?) for the liver daily. He has also had brewers' yeast and a few injections of thiamin chloride. The liver enlargement has receded about one third. The weight has decreased 8 pounds (3.6 Kg.). Would you recommend sugar and salt for this stage of cirrhosis and in a patient overweight and edematous?

W. W. BLACKMAN, M.D., Atlanta, Ga.

ANSWER.—Sugar is unquestionably of value in cirrhosis of the liver and other forms of hepatic disturbance. It probably could be employed to advantage in this case. Salt in the form of ammonium chloride or ammonium nitrate would probably prove effective. These drugs should be given by mouth in large doses over a considerable period but should be employed only under careful medical supervision. Later, at weekly intervals, mercurial compounds of the merbaphen type might be injected to the advantage of the patient, since with their use large quantities of urine are often voided and ascites is relieved. The fluid intake should be restricted.

Since considerable improvement has accrued from the treatment already employed, it might be wiser to continue along the lines established until it is determined how much more benefit from it may be derived. The deep red color of the palms is not characteristic of liver disease. High color (telangiectasia) of the face, on the other hand, is frequently encountered.

YELLOW FEVER

To the Editor:—1. Where can I get the Sawyer immunity test for yellow fever? 2. Where can I get information about the experimental work done in producing encephalitis in mice by inoculation with the yellow fever virus?

EUGENE J. SHANAHAN, M.D., Clyde, Ohio.

ANSWER.—1. The reference is to the protection test in mice by the technic published by Sawyer and Lloyd (*J. Exper. Med.* 54:533 [Oct.] 1931). In the United States this test is being made in connection with research at the laboratories of the International Health Division of the Rockefeller Foundation in New York. Requests for tests of serums in cases of scientific or public health interest should be addressed to Dr. J. H. Bauer, who is in charge of these laboratories, at the Rockefeller Institute for Medical Research, York Avenue and Sixty-Sixth Street, New York, preferably in advance of sending the specimen.

2. The discovery of the susceptibility of mice to yellow fever was made by Max Theiler (*Ann. Trop. Med. & Parasitol.* 24:249 [July] 1930). Since then the mouse has been widely used in geographic yellow fever immunity surveys, production of yellow fever vaccine and research in yellow fever, and an extensive literature has grown up. For information about special parts of the work inquiry may be addressed to the Rockefeller Foundation, 49 West Forty-Ninth Street, New York.

STREPTOCOCCIC TOXINS IN BLOOD

To the Editor:—By what methods can one determine the amount of streptococcic toxin circulating in the blood stream? M.D., New York.

ANSWER.—If the toxin to be assayed is scarlet fever toxin, the blood is drawn and centrifuged after clotting. One tenth cc. of the separated serum is injected intracutaneously in a person giving a positive skin test for scarlet fever susceptibility, and at the same time one skin test dose of scarlet fever toxin is injected intracutaneously in another place in the same person. If a resulting area of erythema at the site of the serum injection is absent or not larger than the area of erythema at the site of the injection of standard toxin, the amount of toxin in the blood is 10 skin test doses per cubic centimeter or less. If it is larger, the serum is diluted to a degree resulting in a cutaneous reaction equal to that of the standard test solution. If it is necessary to dilute 1 to 1 with saline solution there are 20 skin test doses per cubic centimeter of blood.

Erysipelas toxin may be estimated in the same way, standard erysipelas toxin being used as a comparison.

ENDOCRINE TREATMENT OF HYPOGENITALISM

To the Editor:—A white man aged 28 has genitals about the size of the average newborn infant's. Both testicles are undescended. Erection is impossible. Secondary sex characteristics are fairly well developed. The patient has no complaints and is in good physical condition otherwise but wonders if anything might be done to improve his condition. What would you suggest as to therapy and prognosis?

HARVEY L. JORGENSEN, M.D., Marinette, Wis.

ANSWER.—The use of either androgen or the gonadotropic principle of pregnancy urine in the treatment of hypogonitalism (principally during childhood and adolescence) has been successful in many cases. Treatment of the patient with these preparations is worthy of trial and should extend over a period of at least six months. If androgen is used, at least 25 mg., three to four times a week, should be given intramuscularly. If gonadotropic substance is used, from 1,000 to 2,000 rat units should be given every day intramuscularly. The two preparations are equally efficacious. A basal metabolic test should be done and if it is low, adequate doses of thyroid should be given at the same time.

ESTROGENS IN VOMITING OF PREGNANCY

To the Editor:—In the June 25 issue of THE JOURNAL a physician asked the value of estrogen in hyperemesis gravidarum and the suggested dose. The answer stated: "As far as is known, estrus-producing substances have no specific effect in hyperemesis gravidarum. If valuable at all, they most likely act because of their psychic effect." I wish to refer you to a report of fifty cases treated with estrogenic preparations (Hawkinson, L. F.: *Minnesota Med.* 19:519 [Aug.] 1936). These results have recently been confirmed by Shute (*Endocrinology* 21:594 [Sept.] 1937). It seems noteworthy that no adverse report has appeared in the literature during a period of two years. Although the rationale of using estrogen in nausea and vomiting has not been definitely established, the reports of a number of workers who have found relatively low levels of estrogen and high gonadotropic substance in these patients would seem to establish this type of treatment on a clinical basis. Nearly 100 additional cases have been treated in the last two and one-half years and the results continue to be excellent. These patients have been given slightly higher doses than those of the original series. In severe cases daily injections of 10,000 international units of estrogen in oil are given, while in the milder cases the same dose is administered every second to third day.

L. F. HAWKINSON, M.D., Brainerd, Minn.

MALARIA AND VERTIGO

To the Editor:—In Queries and Minor Notes in THE JOURNAL, August 6, appears a discussion entitled "Malaria Not Cause of Vertigo and Restlessness." Your correspondents would draw attention to the fact that Stitt's Practical Blood Work Parasitology contains the following statement: "Hemolysin and endotheliolysin are thrown off at the same time. . . . The endothelial cells take up actively this malarial pigment or hemozoin and are damaged or destroyed thereby. Hematin injections also tend to destroy leukocytes and platelets." McCallum's Pathology states that "at autopsy there is distinct slaty or blackish pigmentation affecting especially the spleen . . . in the brain, the endothelial cells of the capillaries in the brain substance . . ." Boyd's Pathology says "The parasites are most numerous in the capillaries of the brain and the spleen. . . . This is probably the cause of the occasional cerebral symptoms." From the clinical point of view chronic malaria would be an additional cause for arrested digestion and consequent food poisoning with arrest of flow of bile. In chronic malaria disturbing symptoms from the nervous system are only second in constancy to those from the digestive-portal systems in our experience.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, September 17, page 1127.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An affiliate of the American Board of Surgery. New York, Oct. 21-22. Sec., Dr. Paul M. Wood, 745 Fifth Avenue, New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: Written. Various large cities in the country about Oct. 1. Oral. St. Louis, Nov. 11-12. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: Written examinations will be held in various parts of the United States, Oct. 17 and Feb. 20. Application for the February examination must be received on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada, Nov. 5 and Feb. 4. General oral, clinical and pathological examinations for all candidates (Groups A and B) will be given in St. Louis, May 15-16. Applications must be filed not later than sixty days prior to date of examination. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: St. Louis, May 15. Applications must be filed before February 15. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Memphis, Tenn., January. Applications for this examination must be filed with the Secretary on or before Oct. 15. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Washington, D. C., Oct. 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS: Detroit, October 26; Rochester, N. Y., November 13; and Oklahoma City, November 15. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 28-30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF SURGERY: Part I will be given simultaneously in various centers throughout the United States, Oct. 10. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: New York, Jan. 13-15. Applications must be submitted not later than Oct. 1. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Rhode Island July Examination

Mr. Robert D. Wholey, chief, Division of Examiners, reports the oral, written and practical examination held at Providence, July 7-8, 1938. The examination covered twenty subjects and included fifty questions. An average of 80 per cent was required to pass. Nine candidates were examined, all of whom passed. Seven physicians were licensed by endorsement after an oral examination. The following schools were represented:

Book Notices

"Good Morning, Doctor!" By W. A. Rohlf, M.D. Cloth. Price, \$2. Pp. 169, with illustrations. Cedar Rapids, Iowa: Torch Press, 1938.

Here is the magnificently simple story of a great man, though not a prominent man. It is all the more significant because it is typical of the story of country doctors without number who have been serving the people of the United States through storm, flood, disaster and sunshine, through sorrow, perplexity, pain and joy. The story is autobiographic, told with a warm human sympathy delightfully mingled with humor. It is a series of disconnected episodes, which yet give a clear picture of the life of a country boy who struggled against great odds to achieve his ambition to be a country doctor. Typical is the story of his relationship with the clergy. On one occasion he met a minister on his way to the home where the doctor had just attended a patient who died. Dolefully the minister said "First you, then me!" The doctor matches this incident with another, in which he met a minister who had married a couple in whose home the doctor had just attended a birth. To the minister the doctor remarked "First you, then me." These incidents are illustrative of the doctor's close relationship to his patients. In addition to being a physician ready to serve all and sundry under any and all circumstances, he took a keen interest in civic matters. A Boy Scout cabin stands as a memorial to his interest in the Boy Scout movement, in which he is known as Beaver Bill; his friends have erected a stone marker and bronze plaque to commemorate his part in the building of the cabin and in the work of the Boy Scout troop which met in his spacious basement for years. The esteem of his professional colleagues was evidenced in the annual gatherings on his birthday, which grew so large that his home could not accommodate them, and through his election to the presidency of the Iowa State Medical Society. The book is attractively printed and bound and is illustrated with amusing sketches on prescription blanks by one of his associates, who presented him with a book of them, bound with splint boards, catgut sutures and adhesive tape. Such lives as that of this country doctor, who differs from his thousands of colleagues only in that he is more articulate and thus able to put his experiences into this charming chronicle of devotion and service, are a complete answer to the current agitation which would substitute a bureau for the doctor, a dubious efficiency for his unflagging devotion to duty, red tape for human sympathy and understanding, lay control for professional judgment, and politics for the ideals which have made modern medicine what it is. This book should be required reading for all those who, on the basis of little or no understanding, are moving heaven and earth to destroy the profession and the art of medicine.

Les encéphalomyélites de la scarlatine. Par le Docteur Germaine Rambert, de la Faculté de médecine de Paris. Paper. Pp. 139. Paris: Amédée Legrand, 1937.

Two cases are reported; one in a woman 36 years of age who suffered an attack of scarlet fever with stormy onset complicated by nephritis. A severe psychotic disturbance developed. This was unrelated to the febrile period and finally disappeared following an attack of bronchopneumonia. The patient had no personal or family history of mental disease. Samples of cerebrospinal fluid obtained by frequent spinal puncture showed no cellular change. The second case is that of a girl 4 years of age who entered the hospital with an attack of scarlet fever. She became somnolent and had tremor of the hands at the end of the first week when the temperature was falling and the rash fading. The spinal fluid showed 22 cells per cubic centimeter, lymphocytes predominating. A week later unilateral ptosis and exaggerated reflexes were observed. After report-

ing these two cases in detail, the author gives an excellent review of previously reported cases of central nervous system involvement in scarlet fever, classifying them clinically as hemiplegic, convulsive, psychotic, ataxic, diffuse myelo-encephalitic, ocular, neuritic and meningial. Although such complications are comparatively rare in scarlet fever, the possibility of their occurrence should be kept in mind. It is interesting to note that they do not commonly occur during the early, acute stage of scarlet fever but some time later. The author concludes that injury to the central nervous system by toxin during the acute stage of scarlet fever is the determining factor in the later development of such conditions. Scarlet fever antitoxin had not been used in any of the cases reviewed in this work.

A Survey of Methods of Care, Treatment, and Training of the Feeble-minded Together with a Program for the Future Made at Letchworth Village. Thiells, New York. State of New York, Department of Mental Hygiene. Paper. Pp. 164, with 17 illustrations. Utica, New York: State Hospitals Press, 1937.

This report is the result of a request of the superintendent of Letchworth Village for a committee to make a dispassionate and disinterested survey of the institution, in order to bring about a progressive program for the next twenty-five years. Letchworth Village is an institution for the feeble-minded located in New York State, which was founded in about 1909 but was authorized in 1907. It is an excellent, progressive, well developed institution and these characteristics are definitely brought to light by the survey of this investigating committee. Experts in various lines were assembled and, as a result, produced a series of reports dealing first with the physical plant as regards its general plan, architecture, sanitation, mechanical equipment, soil conditions and farming. The second part is devoted to a critical consideration of the care of the patient, the third to educational procedure, the fourth to administration and the fifth to statistics and the research being done at the village. Each one of these topics is disposed of singly by an acknowledged expert in each field and, while one comes to the conclusion that Letchworth Village at the present time is highly adequate in each one of the features considered, suggestions are appended at the end of each part of the survey whereby the institution may further be improved. There is an appendix giving a bibliography of work which has been done by members of the staff of the institution. The value of the report lies, first of all, in giving one an idea of how a modern institution of this kind is set up, all its aspects being dealt with in considerable detail. The actual summarizing of the findings is a revelation on how satisfactorily a survey of an institution may be carried out. There is a third value which may be obtained by carefully culling the suggestions and facts from each of the reports, to determine steps which may be taken in the future in this and other similar colonies to improve the work that is being done to care properly for the feeble-minded.

Alcohol: One Man's Meat.—By Edward A. Strecker, A.M., M.D., Sc.D., Professor of Psychiatry, School of Medicine, University of Pennsylvania, and Francis T. Chambers, Jr., Associate in Therapy, Institute of the Pennsylvania Hospital, Philadelphia. Cloth. Price, \$2.50. Pp. 230. New York: Macmillan Company, 1938.

One of the most encouraging results of the development of modern psychiatric diagnosis and treatment has been a change in the point of view toward alcoholism. Except in a few sanatoriums where the chances of a "cure" were doubtful, little was done until comparatively recently to enable the chronic alcoholic addict to cure himself in order that he might lead a relatively well adjusted life. The senior author of the present book is an able psychiatrist with much experience. He presents for the first time a short, rather simple, volume describing what is being done and what can be done for the alcoholic addict, bearing in mind the new point of view that alcoholism is a mental disease which, in the hands of modern psychiatrists, can be cured in many cases. The present work is not deep. The authors present little scientific evidence dealing with the mechanisms, diagnosis or treatment of alcoholism but rather present, in a very definite fashion, two concepts—the first one comprising about half of the book—the concept of mental disorganization. Alcoholism is a flight from reality or is in other ways a symptom of social and mental maladjustment. The

second concept covers some of the treatment procedures which may be used in correcting this condition. Some of these are encouragement, adjustment of the home situation, particular types of psychotherapy which will enable the man to understand what he is up against and to battle against his problem, hobbies and other technics. These are dealt with briefly. Their rationale is not explained and it is relatively simple material for the experienced psychiatrist. As a whole the book is a level headed, uncomplicated work and can be used with profit by psychiatrists who have a deeper understanding of the mechanisms and methods which the authors only lightly touch on. It is probably the beginning of a series of works which are likely to be published from time to time giving specific directions for treatment and a deeper understanding of the diseases arising from ethylism. There is no bibliography but there are a number of references to the literature in the form of footnotes. There are a few citations of cases but no lengthy case histories. The book is too technical for the layman. It does bring together some material which should be of use to the physician if he has any problems concerning the alcoholic addict. How well the authors' procedures can be followed by others can be determined only by time.

Salaries in Medical Social Work in 1937. By Ralph G. Hurlin, Director, Department of Statistics, Russell Sage Foundation, New York. Paper. Price 20 cents. Pp. 34. New York: Russell Sage Foundation, 1938.

The main purpose of the study was to show how much improvement, if any, was realized in salaries in the field of medical social work between 1933, when the previous study was made, and 1937. No recognized standards of medical social work have yet become general enough to be accepted. The investigation showed that the lowest, median and highest salaries of those investigated were as follows:

Annual Salaries

Position	No. of Workers	Lowest	Median	Highest
Headworker.....	463	\$ 780	\$2,052	\$5,072
Supervisor or assistant headworker.....	61	1,500	2,160	3,700
Caseworker.....	1,037	720	1,632	2,700
Psychiatric caseworker.....	120	808	1,834	2,850
Clinic worker.....	83	672	1,560	2,472
Admission worker.....	57	840	1,560	2,850
Worker in training.....	32	624	1,440	1,740
Total.....	1,533			

Salaries of all the classes of workers showed increases during the last four years, the greatest increase being for "headworkers," among whom it amounted to about 11 per cent. The number of medical social workers increased 8 per cent.

Diet and High Blood Pressure. By Dr. I. Harris, Honorary Physician, Liverpool Heart Hospital. Cloth. Price, \$3.50; 10s. 6d. Pp. 196. Toronto: Longmans, Green & Co.; London: Hogarth Press, 1937.

This little book is prepared for lay consumption. In it Harris tries to preach his gospel with a fervor and enthusiasm truly unitarian in point of view. His "theories" anent the pathogenesis of arterial hypertension, as presented in an earlier, more medical, monograph ("High Blood Pressure"), have been previously reviewed in *THE JOURNAL* (Oct. 23, 1937, p. 1389). Therein he attempts to convince by reiteration that the primary etiologic responsibility in hypertensive arterial disease rests on high protein dietary and the renal injury through the implied necessity of increased renal work in excreting larger quantities of nitrogenous debris and especially urea. In the previous review it was remarked that this thesis is untenable in the light of modern scientific knowledge of hypertensive arterial disease. Harris's little book is fruitful of such dogmatic and almost bigoted statements as "All that is necessary, so far as eating is concerned, is that *everybody* should realize that *every* morsel of food taken which is unnecessary damages the human machinery" and "I am happily in a position to give definite guidance in regard to food, which, if acted upon, I *know* will reduce the incidence of high blood pressure materially and prolong life" (italics by the reviewer). Elsewhere he becomes poetically prophetic over the immense benefits to be derived if every one would but follow his regimen blindly. There are portions here and there where

his advice appears sound and logical, particularly anent the fluid intake and in certain of the appended diet tables. But the book as a whole has little merit and is pedantic, misleading and biased with unproved theory. To the reviewer the whole manner of presentation is that of a sincere but misled zealous faddist. The evils of obesity are distorted as though the satisfaction of a hearty gastronomic appetite were a cardinal sin.

A Textbook of Histology. By Alexander A. Maximow and William Bloom, Associate Professor of Anatomy, University of Chicago. Third edition. Cloth. Price, \$7. Pp. 668, with 542 illustrations. Philadelphia & London: W. B. Saunders Company, 1938.

The late Professor Maximow had begun before his death a textbook of histology, which was completed by Bloom in 1930 and which was so successful that a second edition appeared in 1934. Continued advances in histology necessitated an extensive revision for the third edition. Prof. C. Judson Herrick, who wrote the chapters on the nervous tissues for the previous editions, is replaced by Prof. Stephen Polyak. It is almost impossible to express adequately the fine organization and beautiful illustration of this textbook. Although of course it would be thoroughly inadvisable for a medical student to study histology without actually seeing the tissues under the microscope, if the latter were impossible the book is so profusely illustrated that a student could get, by studying it alone, a remarkable mental picture of the microscopic appearance of tissues. The attempt to avoid most controversial issues while keeping the book abreast of the advances in histology and histophysiology has been generally successful. While the book can need no recommendation for medical students, it may also be extraordinarily useful to those who have occasion to review and extend their knowledge of microscopic anatomy. For purposes of reference the index is entirely adequate.

Seibzehn Jahre Strahlentherapie der Krebse; Zürcher Erfahrungen, 1919—1935. Von Hans R. Schinz und Adolf Zupplinger. Paper. Price, 32 marks. Pp. 340, with 95 illustrations. Leipzig: Georg Thieme, 1937.

This book gives a survey of 2,529 patients admitted for radiation therapy during the years 1919 to 1935 in the Roentgen Institute of the University of Zurich. This institute functions as the central radiotherapeutic unit for a large part of Switzerland. The book represents an important contribution to the radiologic literature, as it gives a critical and honest cross section showing the radiotherapeutic possibilities up to the time of publication in an unselected material in which only 1.7 per cent of patients were not followed. Every case admitted to the institute is accounted for. The cases treated by the authors were particularly unfavorable for therapy because the most favorable lesions for radiation therapy, such as carcinomas of the skin and cervix, represent only a small minority of their cases. Most of these lesions were treated in the gynecologic and dermatologic clinics. Most of the cases in general were in a far advanced stage of disease, as evidenced by the fact that only 24 per cent of them were technically operable. Cancer of the upper respiratory tract and pharynx represent about 30 per cent of the material, breast carcinoma 16 per cent, carcinoma of the esophagus and gastrointestinal tract 10 per cent; only 5 per cent were carcinomas of the skin and natural openings of the body and 1 per cent carcinoma of the cervix. Eighty per cent of the patients were treated by radiotherapeutic procedures exclusively, 20 per cent in combination with surgery. The basic radiotherapeutic procedure used was roentgen therapy, which was indicated in 85 per cent of all cases, whereas a local radium application alone or in combination with x-rays was used in approximately 15 per cent. The radiation technics employed were used consistently over a period of years without rapid change of the technical procedure, in this way allowing definite conclusions as to the value of the method.

During the first period covered by the report, from 1919 to 1928, the treatment was given in the form of large doses followed by smaller additional doses. Since 1928, following Coutard's experience, the treatment was consistently conducted in a protracted fractional form over several weeks. Alive and symptom free three years after treatment, or dead from intercurrent disease after a three year symptom free interval, were 17 per cent of all patients treated, 13 per cent after five years. The cure rate in the operable cases was 43 per cent, in the inoperable ones 9 per cent. Favorable palliative results were accomplished

in 54 per cent of the cases. This amounts to a favorable effect, either palliative or curative, in 70 per cent of the cases. It is interesting to compare the improvement of the results with the improvement in the therapeutic procedures, as can be seen from a comparison of the results in the first period of treatment before 1928 with the second period, as indicated by only 11 per cent symptom free for at least one year during the first period and 30 per cent during the second period. For certain locations, such as the pharyngeal and laryngeal carcinomas, the difference is considerably more marked than in this average.

The results in tumors of different locations are carefully arranged in detail.

The Patient and the Weather. By William F. Petersen, M.D. With the assistance of Margaret E. Milliken, S.M. Volume IV, Part 3: Organic Disease; Surgical Problems. Cloth. Price, \$10. Pp. 651, with 482 illustrations. Ann Arbor, Michigan: Edwards Brothers, Inc., 1938.

The earlier volumes of this massive work have been reviewed in these pages. Like the others, the present work is a thoroughgoing highly developed analysis of the relationship of certain clinical changes with regard to changes in temperature, polar fronts and other meteorological changes. The book is full of case histories, including reports from the literature; there are a number of graphs in which changes in the weather are correlated with changes in clinical signs; there are several tables, all of which have to do with the thesis which this author has been following for so many pages that weather changes are accompanied by vascular changes which aggravate symptoms and in many cases actually change the course of a disease. The topics covered in this book are infection, inflammation, ulcer of the stomach, Meckel's diverticulum, gallbladder disease, acute pancreatitis, appendicitis, ectopic pregnancy, postoperative complications, vascular accidents, drain abscess, meningitis, orthopedic cases and ophthalmologic episode. There is also a chapter entitled "Endemiology of the Surgical Diseases." This is a scholarly and deep work. The points brought out by the author are illustrated by groups of thoroughly discussed individual cases rather than statistics, and the surgeon should be interested in following up Petersen's ideas on this subject.

Introduction to Ophthalmology. By Peter C. Kronfeld, M.D., Professor of Ophthalmology, The Peiping Union Medical College. Cloth. Price, \$3.50. Pp. 331, with 37 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1938.

From his long experience as a teacher of ophthalmology in Chicago and Peiping, from his varied clinical research work and from his intimate knowledge of both the American and the Viennese schools, the author has produced a textbook which is unquestionably one of the finest of recent works for the medical student of ophthalmology. While the book is intended as "a formulation of principles," it goes much further and provides rational physiologic and clinicopathologic explanations of the difficult problems which confront a physician attempting to gain a useful understanding of the eye and its diseases. The author presents clearly and in a most practical manner the problems of conjunctivitis, which are so important for the general physician. Diseases of the cornea are well described and the subject of interstitial keratitis is given special consideration. The subject of cataract is particularly well discussed. The chapter on injuries should give the general physician a clear understanding of the mechanism of certain eye injuries and particularly of the dangers to the uninjured eye from sympathetic ophthalmitis. The presentation of diseases of the retina is one of the best sections of the book. After devoting a chapter to the physiology of the retinal circulation, Kronfeld discusses admirably the vascular diseases of the eye—the retinal conditions associated with arteriosclerosis and arteriolar sclerosis, hypertension, nephritis and diabetes. The important problem of the pathologic physiology of glaucoma is discussed rather completely. The author treats fully some of the diseases of the optic nerve and clarifies the problem of papilledema. His treatment of some of the practical problems of neuro-ophthalmology is succinct. A chapter is devoted to the pupil as a neuro-ophthalmologic entity which should be useful for the general physician. Of particular benefit to the student is the way in which the author has incorporated comparative data in instructive tables and has tabulated the differential diagnostic points

in diseases with similar symptoms and signs. A number of Bertha Klien's fundus drawings illustrate admirably certain diseases of the fundus in spite of the fact that they are uncolored. Students and practitioners of medicine should read and study this splendid volume with pleasure and profit.

Emergency Surgery. By Hamilton Bailey, F.R.C.S., Surgeon, Royal Northern Hospital, London. Third edition. Cloth. Price, 50s. Pp. 852, with 816 illustrations. Baltimore: William Wood & Company, 1938.

This is an extremely workmanlike and practical treatise on emergency surgery. It reflects vividly the large experience and the thoughtfulness of its author. In its fifty-three chapters the entire field of surgical conditions requiring immediate treatment is carefully discussed. Every surgeon will find it enjoyable and profitable reading. The chapters dealing with acute appendicitis and intestinal obstruction are particularly praiseworthy. The illustrations, many of which are in color, are numerous and informative. The frequent use of well chosen illustrative cases vivifies and accentuates the subject matter. Greatly to be commended are the valuable references at the end of each section. It is difficult to find fault with this splendid book, but the reviewer is disturbed by the recommendation of intravenous mercurochrome and the unfortunate omission of the continuous indwelling suction apparatus of Wangenstein. Moreover, he deprecates the transperitoneal drainage of appendical abscess in one stage. It would seem preferable to pack gauze down to the abscess and allow it to discharge spontaneously after the general peritoneal cavity has been well walled off.

Hemorrhoids. By Marlon C. Pruitt, M.D., L.R.C.P., F.R.C.S., Associate in Surgery, Emory University School of Medicine, Atlanta. Cloth. Price, \$4. Pp. 170, with 73 illustrations. St. Louis: C. V. Mosby Company, 1938.

In the text of this volume the author does not pretend to present anything new. He states in his preface that "the questions now are what are the comparative values of the various methods advocated, and is one method more suitable than another for a certain kind of case?" Most of the methods described, as well as the illustrations, are taken from other books with acknowledgment. Much of the remainder of the text and most of the remaining illustrations present features embodied in discussions and illustrations that have been published in other books. The volume presents a fair recapitulation of some of the accepted facts and methods on the subject of hemorrhoids.

Everyday Terms in Economics. By Cornelius C. Janzen, Ph.D., Head Department of Economics, State Teachers College, Milwaukee, Wisconsin. Paper. Price, 50 cents. Pp. 75. Chicago: Thiesens Printing Corporation, 1938.

More than 800 terms commonly used in economics and business are defined in what may be looked on as the beginning of a handy dictionary of economics. While some schools of economics would doubtless quarrel with a few of the definitions, the author seems to have steered a middle way which will make his work helpful to members of all schools. The advanced student will be somewhat disappointed to note the omission of some of the newer terms about whose meaning he is most apt to be in doubt.

Oxygénothérapie et carbothérapie: Bases physiologiques; applications cliniques; techniques. Par L. Dautrebande, professeur à la Faculté de médecine de l'Université de Liège. Paper. Price, 55 francs. Pp. 300, with 82 illustrations. Paris: Masson & Cie, 1937.

Despite the great interest of the medical profession in inhalation therapy, only a few good monographs on this subject are available. Dautrebande was especially well qualified to write a book on oxygen and carbon dioxide therapy, on the basis of his excellent physiologic background, remarkable knowledge of the literature on the subject, and special interest in the field of group oxygen therapy, to which he was led by his study of war gas poisoning. The first six chapters, presenting the physiology of transport of respiratory gases, the pathophysiologic changes resulting from oxygen want, the effect of carbon dioxide on respiration and circulation, and the physiologic basis for the use of oxygen and carbon dioxide, are excellent. Scant attention, however, is paid to the part played by the breathing mechanism in alveolar ventilation. In the next chapters, VII, VIII, IX and X, a list and a discussion of the clinical conditions in which

oxygen and carbon dioxide therapy has been advocated is presented. These chapters appear to be based more on an extensive knowledge of the medical literature than on personal acquaintance with the practical side of the problem of inhalation therapy (indications, choice of methods and duration of treatment). In the last two chapters, on the technic of administration of oxygen and carbon dioxide, great emphasis is given to masks and catheters, little to oxygen tents and rooms. The army surgeon will find much of interest in reading the chapter on collective oxygen therapy. Clearly written and abundantly illustrated, this book ends with an excellent bibliography (especially English and French). As a whole, this work deserves commendation.

Miscellany

THE WORK OF THE COMMISSION ON STANDARDIZATION OF BIO- LOGICAL STAINS

H. J. CONN, Ph.D.

Member of Biological Stain Commission
GENEVA, N. Y.

Many physicians are not familiar with the work which has been in progress for over fifteen years under the direction of the Commission on Standardization of Biological Stains; nor perhaps is it generally realized what services this organization is able to perform for doctors. Not all physicians use stains in their work, but even if they do not do so themselves they are quite likely to submit specimens for diagnosis to some laboratory where these products are employed. The Stain Commission proposes to see that the stains obtained by laboratories are dependable. Much of the information given here has been published before¹ but not in sources readily available to the physician.

Not until after the World War, which excluded German dyes from America, did any thought of standardizing biologic stains occur to biologists. Until then it was quite generally accepted throughout the biologic world that for staining purposes the dyes put out by Dr. Grübler of Leipzig were sufficiently standardized, although it has since been learned that these stains were not only lacking in uniformity but sometimes even mislabeled.

The need of standardization was first brought to the attention of American biologists by the exclusion of German dyes during the war and the postwar period of complete embargo on such products, when it was found that the domestic stains were not sufficiently uniform to be reliable. This problem did not become acute in America until the prewar stock of German stains had become exhausted, which did not occur until about 1918-1920. When German stains became available again in the United States it was found that another factor of uncertainty had been introduced, owing to the fact that Dr. Grübler had fathered two concerns, one originally a laboratory manufacturing certain biologic products, the other a company doing no manufacturing but concerned merely with the distribution of stains. It was learned after the war that each of these organizations was selling a complete line of biologic stains and the rival claims of the two added to the confusion of biologists.

To eliminate some of this confusion the Commission on Standardization of Biological Stains was organized by the National Research Council in December 1921. This commission was established as an organization to coordinate the work on stains in which various American scientific organizations were interested. Those at present represented on the Stain Commission are the Society of American Bacteriologists, the American Medical Association, the American Association of

1. Conn, H. J.: Progress in the Standardization of Biological Stains: The Certification of Stains, *Stain Techn.* 9: 81-88, 1934; Recent Advances in the Standardization and Improvement of Biological Stains, *Botanical Review* 3: 72-83, 1937.

Anatomists, the American Association of Pathologists and Bacteriologists, The American Chemical Society, the American Public Health Association, the American Pharmaceutical Association and the American Society of Zoologists. A representative of each of these societies serves on the executive committee of the commission. Other members of the commission are biologists or chemists known to be interested in stains or staining whose names are voted on for membership by the executive committee. Some of these members assist in the testing of stain samples submitted for certification, although by no means the entire membership has ever been called on for this purpose.

The Stain Commission was enabled to get started through the generosity of the Chemical Foundation, from which it has received in all something like \$100,000. At the present time, however, the commission is gradually becoming self supporting, its income deriving from sale of publications and charges made to stain companies whose products are tested. It is hoped to make it completely self supporting within the next few years.

The samples of stains which are tested by the commission, to learn whether or not they deserve certification, are submitted by the stain companies whenever a new batch of any stain has been manufactured. Certification is therefore carried out entirely on a batch basis. No stain company has ever been given a blanket certification for its entire production of any particular dye. This plan of certifying each batch individually was adopted at the beginning of the work because chemical tests were not known which would properly distinguish between satisfactory and unsatisfactory samples. It was realized that the most painstaking and conscientious manufacturer of dyes could not be absolutely certain of duplicating exactly a satisfactory sample of stain.

Today, however, it is often possible to be reasonably certain as to the performance of a stain from certain simple tests. Samples sent to the Stain Commission for certification are submitted to two general types of tests: (1) physicochemical; (2) biologic. An associate, who is located at Washington, D. C., performs the physicochemical tests in a laboratory of the U. S. Department of Agriculture. These tests are both chemical and optical and have been developed little by little in the course of the work as giving the most useful information in the case of each particular dye. The biologic tests are more varied than the chemical tests because comparatively few of the dyes are used by biologists in identical procedures, and this has made it necessary in many cases to test a stain by some method that is used for no other dye. It is considered particularly important, therefore, to determine the performance of each stain in the procedures for which it is ordinarily employed in the biologic laboratory. The methods of testing have been published elsewhere.²

Those batches of stains which prove satisfactory by these tests the Stain Commission allows to be sold under its certification. This certification is indicated by a label printed on a special paper which bears the seal of the Stain Commission as a background design. Each label has the signature of the chairman of the commission on its face. Any one buying a stain bearing this certification label of the commission can be sure that the dye is true to type and that the batch from which the sample was obtained has been found satisfactory by biologists for the purposes for which that particular stain is ordinarily employed.

An advantage in employing a certified stain is that the dye content is given on the label whenever methods for determining the dye content of that particular dye are available; also all certification labels bear some general statement as to the purposes for which the stain is intended. The use of a certified stain assures the purchaser that if the stain proves unsatisfactory he can make his complaint to a disinterested body with experi-

ence to tell him whether his trouble arises from faulty technic or from some other source.

Especially important to the user of stains is the fact that unsatisfactory batches do not secure the approval of the commission. When the work was started, a fairly high percentage of samples were rejected as unsatisfactory. This proportion decreased at first but has now remained fairly steady for several years at about 10 per cent of all the samples submitted. The reason for the rejected samples is not because any of the stain companies are unreliable but because of the difficulty of securing absolute uniformity in the manufacture of this type of chemical. As a matter of fact, the stain companies have always been very anxious to put out as reliable products as possible. Those batches that are rejected by the commission are either withdrawn from the market entirely or, as in the case of some stain companies, are sold at a lower price without the commission certification.

This system of certification has worked to very good advantage from the standpoint of the laboratory worker who uses stains to such an extent that it is economical to buy the solid dyes and to make up his own staining solutions. It does not, however, work so well in the case of the physician who may occasionally, for example, have need for 1 or 2 cc. of a blood stain or perhaps of a methylene blue solution. Stain companies report that there is coming to be more and more demand for staining solutions sold in 1 ounce bottles. Presumably these are purchased by individuals who have an occasional need for examining a stained preparation under the microscope but do not do so often enough to purchase dry stains or larger quantities of staining solutions. Whether the purchasers of these ounce bottles are physicians or laboratory workers who employ stains only occasionally is a question to which the answer has not yet been obtained.

The executive committee of the Biological Stain Commission feels that, although it has already accomplished something worth while in making available a supply of reliable stains in solid form, the commission has not accomplished its full purpose if the demand for stains in solution form is increasing and the solutions at present on the market are not entirely reliable. Accordingly, plans are at present under consideration for extending the system of certification in such a way that purchasers of solutions may have a fair degree of confidence as to the quality of the stains they are getting, even though staining solutions cannot be guaranteed to quite the extent that solid dyes can.

There are difficulties, however. Many staining solutions do not keep well, and even if they do their bulk makes it impracticable for a lot to be made up of sufficient size so that approval can be put on a batch basis as in the case of the solid stains. For this reason the plans for the approval of staining solutions are being made slowly and certain information is still necessary before they can be put into practical effect. The information most needed would be obtained if reliable answers were secured to the following three questions:

Which staining solutions as purchased at present give most trouble?

Who are the ultimate consumers of stains purchased in this form (i.e., doctors or laboratory workers)?

What is the most popular size package among purchasers of such solutions?

If answers to these questions are secured and it is found that physicians are the large users of stains as sold in 1 ounce packages, it is hoped that some plan can shortly be adopted for assuring purchasers of the reliability of such solutions on the market and that an announcement concerning this plan can be made at an early date.

Those interested in the subject and having information that may help in answering these questions are invited to communicate with the author of this article.

MEDICOLEGAL ABSTRACTS

Hospitals for Profit: Necrosis Following Hypodermoclysis.—The plaintiff, a woman of about 60 years of age, underwent a kidney operation in the defendant hospital. Shortly after the operation, a hospital intern and a nurse, at the direction of the operating physician, administered 1,000 cc. of normal saline solution in the plaintiff's pectoral region, just below the breast. There were no undesirable after-effects. Two days later, another hypodermoclysis was administered by the same intern with the assistance of a nurse, this time in the front medial portion of each thigh of the plaintiff. After about 600 cc. of the solution had been administered, the intern ordered the nurse to stop the administration because of the intense pain suffered by the plaintiff. An examination disclosed areas of puffed and discolored tissue about 4 inches in diameter around each of the places where the needles had been inserted. In the course of the next few weeks, the skin and subcutaneous tissues in those areas became necrotic. Following an excision of the necrotic tissue, skin was grafted in the resulting craters, both of which healed. Alleging that the necrosis was the result of the defendant's negligence, the plaintiff instituted a suit for damages. The jury returned a verdict for the defendant, and the plaintiff appealed to the Supreme Court of Minnesota.

There was no direct evidence, the court said, that the fluid introduced into the plaintiff's body was not normal saline solution. The fact that no test of the solution was made was not evidence that it contained a harmful substance, nor was the fact that suffering accompanied its administration evidence of negligence. The medical experts for both sides testified that necrosis is not produced solely by actively destructive substances; it may be produced by any condition obstructing or destroying the circulation of the body fluids through the tissues. Fluids absorbed from the blood by the tissues are carried back into the blood circulation by means of lymphatic vessels. If those vessels are obstructed or if the fluid content of the tissue is so great that they cannot carry it off, or if the circulation of the blood is inadequate, the tissues become water logged and incapable of absorbing from the circulating blood the nourishing fluid necessary to enable them to live and function and since the tissues require the nourishment carried by the blood, they die if they cannot obtain it. Thus an inert solution introduced into a tissue may cause necrosis if its presence impedes or blocks the circulation of the blood through that tissue.

At the time the plaintiff entered the hospital, she was more than 30 pounds overweight. She had undergone a serious operation the previous summer. At the time of her admittance she was not only suffering from a pathologic kidney condition but was also afflicted with edema of the legs and ankles. The record disclosed that sometimes necrosis will follow a hypodermoclysis even though due care is used and no complicating factors are apparent. It was fairly inferable to the court that the necrosis complained of in the present case resulted from the edematous condition of the plaintiff's thighs. Edema indicates that the tissues are overcharged with fluid and that the patient's circulation is not strong enough to correct it. The instillation of still more fluid into those tissues would have the effect of further burdening the tissue and of further curtailing circulation to those regions, with necrosis of those tissues as a result.

Despite the fact that the unfortunate result might by inference be attributed to other causes, the plaintiff insisted that the jury should have been permitted to infer from the fact that injury resulted that it was caused by some solution other than normal saline; and that the jury should have been permitted to infer further, from the "fact" established by this first inference, that the defendant was negligent in administering this harmful solu-

tion. This insistence was in effect, the court pointed out, an assertion that the doctrine of *res ipsa loquitur* applied to the case. But, the court said, that doctrine permits the inference of a fact from an occurrence only when there is no other probable cause of the occurrence. Negligence will not be presumed from the fact that treatment by a physician does not result in a cure. An inference of negligence based on an inferred fact of which there is neither evidence nor predominating probability cannot be safely made. The trial court, in the opinion of the Supreme Court, was correct in limiting the issue to the question whether the defendant was negligent in failing to terminate the hypodermoclysis at an earlier time, and that issue was decided adversely to the plaintiff. The judgment of the trial court for the defendant was therefore affirmed.—*Collings v. Northwestern Hospital (Minn.)*, 277 N. W. 910.

Malpractice: Failure to Use X-Rays in Extracting Third Molar.—The plaintiff went to "Dr. Adams Dentists and Associated Dentists" to have fourteen teeth in his lower jaw extracted. A gas anesthetic was administered and a dentist, Sanborn, proceeded to extract the teeth. He experienced difficulty in extracting the third molar on the right side, the forceps slipping off the tooth six or seven times, so far as the patient could determine. The patient sensed a cracking sound when the molar finally came out and he told Sanborn that he believed his jaw was fractured. No examination was then made nor was one made when two days later he renewed his complaint, but he was assured that he would be all right in time. Four days after the extraction he went to a hospital and there it was discovered that his jaw was fractured and that osteomyelitis had developed. He brought an action for malpractice against "Dr. Adams Dentists and Associated Dentists" and Sanborn. From a judgment in favor of the patient the defendants appealed to the Supreme Court of Michigan.

Sanborn testified that the tooth had only partly erupted. He could tell, he testified, from looking at the tooth in what direction the roots were going and he knew in this case that it would take extra effort to extract it. He experienced some difficulty but no more than usual for that type of tooth. In his judgment there was nothing to warrant the use of x-rays and nothing that led him to believe that the jaw was fractured.

The fracture of the jaw in extracting the impacted wisdom tooth, said the Supreme Court of Michigan, did not in and of itself establish negligence. The plaintiff recognized that to establish negligence it would be necessary to show that Sanborn failed to follow the usual and ordinary practice of dentists of average ability practicing in that or similar localities and also that the alleged negligence was the proximate cause of the injuries. He called various experts, who testified as to what might be called approved practice in the vicinity. His allegation of malpractice, however, seemed to rest on the testimony of only one. That witness testified that "A good operator would never proceed when he runs into difficulty, without stopping and taking an x-ray," but his testimony lost probative force through his answers to questions propounded by the plaintiff's own counsel. When he testified, for instance, that perhaps Sanborn would not have done all he did do and used the same instruments and the same method of procedure if he had had the benefit of the use of x-rays, his answer, said the court, was conjectural as to whether or not an x-ray would have dictated a different method than the one employed. Adjudicated malpractice must rest on negligence in commission or omission. When charged on omission, it must be made to appear that the negligence was the proximate cause of the injury. The dental establishment of defendant Adams had an x-ray apparatus available for use by the operator in case of need, but it was not employed in the instance here involved because Sanborn by view and manipulation of the tooth, according to his testimony, was aware of the full situation and knew what forceps would fully meet it. If so, Sanborn extracted the tooth with such knowledge as the x-rays would have afforded. There was no showing that x-rays would have led to a different method of operation and therefore

the charge of malpractice resulting in a fracture of the jaw was based on mere conjecture.

The damages awarded the plaintiff, said the Supreme Court, were awarded both for malpractice in extracting the tooth and for postoperative negligence. The award was in one sum and cannot now be separated so as to distinguish the amount awarded for each charge. The evidence did not warrant the jury in finding the defendants guilty of malpractice in extracting the tooth, and the trial court should have granted a new trial. The judgment in favor of the plaintiff was accordingly reversed and a new trial granted.—*Dunbar v. Adams (Mich.)*, 276 N. W. 895.

Evidence: Admissibility of Death Certificate.—The state of Maryland, on behalf of the parents of a child who drowned in a swimming pool owned and operated by the city of Baltimore, brought suit against the mayor and the city council of that city. From a judgment in favor of the plaintiffs, the mayor and the city council appealed to the Court of Appeals of Maryland.

It was contended, among other things, that the lower court had erred in admitting in evidence a transcript of a death certificate, issued by the health department of Baltimore, in which appeared the statement that an autopsy had disclosed drowning as the cause of death. The transcript, said the Court of Appeals, was not authenticated. It was therefore hearsay and irrelevant and should have been excluded. Even assuming that, under Code Pub. Loc. Laws, art. 4, sec. 31, a properly authenticated death certificate would have been admissible, the finding of the coroner as to the cause of death was not. Although the court was of the opinion that the lower court had erred in admitting the transcript, it did not deem the error a reversible one. The judgment in favor of the plaintiffs, however, was reversed on other grounds.—*Mayor and City Council of Baltimore City v. State, for use of Bluford et al. (Md.)*, 195 A. 571.

Partnerships: Enforceability of Agreement Not to Engage in Practice.—In September 1934 the plaintiff, a licensed physician, agreed to buy a hospital owned by the defendant physician, and as a part of the same transaction the parties entered into a partnership for general and office practice and obstetrics but not for the practice of surgery. The parties further agreed that on the dissolution of the partnership the defendant would either repurchase the hospital from the plaintiff at the price he paid for it or would refrain for five years from practicing medicine within 100 miles of Pryor, Mayes County, Okla., the town in which the hospital was located and in which the partnership practice had been carried on. The hospital was conveyed to the plaintiff in September 1934 and the plaintiff and defendant began practice as partners, but their entire agreement was not reduced to writing until Jan. 7, 1935. The contract thus evolved, without legal advice, was described by the court as "obviously a layman's agreement" and "not a gem of perfection." In May 1935, by mutual consent, the partnership was dissolved, but the defendant physician refused to repurchase the hospital and continued to practice in the locality. The plaintiff then petitioned the district court, Mayes County, to enjoin him from so practicing, which the court did. The defendant appealed to the Supreme Court of Oklahoma.

Oklahoma statutes (sections 9493 and 9494, O. S. 1931 [15 Okla. St. Ann. sections 218 and 219]) provide that one selling the goodwill of a business may agree with the buyer not to engage in a similar business in a specified county, city, or part thereof, within a reasonable period of time. The defendant, apparently relying on these statutory provisions, contended that, inasmuch as the agreement in the present case contained no provision for the sale to the plaintiff of the goodwill of the defendant's business, such sale was not contemplated by the parties. The Supreme Court, however, held that even though a contract for the sale and transfer of a business omits to mention the goodwill, the presumption is that it was the intention of the parties that the goodwill should pass with the other assets. The defendant further contended that since the sections referred to authorize only agreements not to engage in business

in a specified county or city, or in a part of a county or city, the present agreement was void, because it undertook to prohibit the defendant from engaging in practice within 100 miles of Pryor. The fact, said the Supreme Court, that the contract takes in too much territory does not render it wholly void but void only to the extent that it prevents the defendant from practicing medicine beyond the limits fixed by law, that is in this case the county.

Apparently after the partnership was dissolved and before the plaintiff had instituted this present action, the parties entered into a written stipulation under which it was agreed that the defendant might use the plaintiff's hospital for the treatment of his, the defendant's, patients but that the stipulation was not to be construed as a waiver on the part of either party of his rights under the written agreement of January 1935. The defendant, notwithstanding the terms of this agreement, asserted that, by thus agreeing to accept benefits from the defendant's practice, the plaintiff was barred from contending that the defendant's practice was in violation of the agreement into which they had entered in the first instance. With this contention, the Supreme Court did not agree. Consent by the plaintiff to the use of his hospital for professional purposes amounted to nothing more than commendable professional courtesy, and there was no evidence that the defendant had been misled or injured by the arrangement such as would be necessary to bar the plaintiff's contention.

For the reasons stated the injunction restraining the defendant from practicing was affirmed but only so far as related to Mayes County.—*Herrington v. Hackler (Okla.)*, 74 P. (2d) 388.

- Vermont State Medical Society, Burlington, Oct. 6-7. Dr. B. F. Cook, 154 Bellevue Ave., Rutland, Secretary.
- Virginia Medical Society of, Danville, Oct. 4-6. Miss Agnes V. Edwards, 1200 East Clay St., Richmond, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Aneurysm of the Heart: Clinical Recognition of Aneurysm of Left Ventricle. D. Ball, New York.—p. 203.

*Electrocardiographic Findings in Forty-Four Cases of Trichinosis. C. H. Beecher and E. L. Amidon, Burlington, Vt.—p. 219.

Cardiac Syncope Due to Paroxysms of Ventricular Flutter, Fibrillation and Asystole in a Patient with Varying Degrees of Auriculoventricular Block and Intraventricular Block: Report of Case. G. Gertz, H. A. Kaplan, L. Kaplan and W. Weinstein, Chicago, Ill.—p. 225.

Erythralgia of the Extremities.—Smith and Allen believe that erythralgia is a more descriptive term than erythromelalgia for the syndrome of heat, redness and pain of an extremity. This syndrome, which may affect one or more extremities, is characterized by discoloration and distress, both of which are dependent entirely on the temperature of the skin, the increase of which constitutes the third component. The condition may occur as a primary disturbance or it may be secondary to such conditions as polycythemia vera. The diagnosis depends on the establishment of a close relationship between the occurrence of the distress and the temperature of the skin. When the temperature of the skin increases above a critical point, the distress occurs; when it decreases below the critical point, the distress disappears. The distress itself results from a susceptible state of the skin to increased temperatures, a condition which does not occur in normal persons. Treatment is not uniformly successful. It is important to determine whether there is any condition such as polycythemia to which erythralgia might be secondary. Under such a circumstance the treatment of the syndrome affecting the extremities would be the treatment of the condition which produces it. Surprisingly, acetylsalicylic acid in amounts of 10 grains (0.65 Gm.) may produce marked relief which persists for as long as several days. No adequate explanation of this is available. Some symptomatic relief may be obtained by avoiding procedures that produce vasodilatation in the extremities. Avoidance of exposure of the feet to warmth, as in riding in the front seat of an automobile, may alleviate some of the distress, as may also the use of light socks or stockings and of sandals or perforated shoes. When simple measures fail, it may be necessary to anesthetize the skin of the feet by section, crushing or by the injection of alcohol into such peripheral nerves as the posterior tibial, peroneal and sural. A logical method is to attempt to desensitize the skin to heat.

Electrocardiograms in Trichinosis.—Beecher and Amidon present the electrocardiographic observations of forty-four patients with trichinosis in the second and ninth weeks of their illness. All these patients were previously apparently healthy persons from 17 to 20 years of age. They had recently passed physical examinations, at which time no evidence of cardiac disease had been found. In none of the tracings were there definite changes in the T wave in lead 2, nor were the amplitudes of the QRS waves abnormally low. In case 4 the first electrocardiogram showed frequent premature contractions of the nodal type. There was no history of cardiac irregularity before this illness, and on the patient's discharge from the hospital the pulse was again regular, as indicated by the second electrocardiogram that was taken. In case 36 the PR interval was found to be above the normal limits in the first tracing, but it had returned to normal limits on the second examination. In this case splintering was noted on the first tracing in leads 2 and 3 and was not found when the second examination was made.

Bile Salt Therapy in Gallbladder Disease.—Doubilet and his associates report thirty-eight cases of pain and dyspepsia after cholecystectomy, in the majority of which relief was obtained by a fat free diet and by an adequate intake of bile salts. Certain exceptions must be observed. If a choledochal stone is present, the increased flow of bile following the administration of bile salt results in an accentuation of symptoms or even the appearance of jaundice. Any condition, such as partial stricture, malignant growths or chronic pancreatitis, which would diminish the diameter of the common bile duct could cause an increase in symptoms after treatment with bile salt. The presence of gastric hyperacidity renders treatment difficult. In such cases the frequent attacks of pain seem to be due to the recurrent spasm of the sphincter of Oddi. The addition of atropine and alkalis to the therapy is of great assistance. The neurotic patient is also difficult to treat, since any emotional upset brings on an attack of pain. This is apparently due to a spastic condition of the gastrointestinal tract which involves, among other sphincters, the common duct sphincter as well. It would seem that the increased flow of bile from the liver, the disappearance of the difficulty in digestion and the improvement in intestinal peristaltic action all tend to eliminate the tendency to gastrointestinal spasm. In support of this it has often been noted that the relief of constipation only by the ordinary saline cathartics is occasionally of some assistance in the improvement of painful symptoms. The removal of a functioning gallbladder containing a few stones should be deprecated on general physiologic principles. Medical therapy should be attempted before operation is advised. However, the treatment of patients suffering from disease of the gallbladder cannot be condensed to a few directions; but, if one keeps constantly in mind the known physiologic principles of the biliary and gastrointestinal tracts, one can achieve considerable success in the therapy of disease of the gallbladder.

 Results of Nonspecific Treatment in Dementia Praecox. C. O. Cheney and P. H. Drewry Jr., White Plains, N. Y.—p. 203.

Hydrotherapy in Delirium Tremens.—Bell and Talkington treated 112 consecutive patients admitted with a diagnosis of delirium tremens by hydrotherapy. The treatment consisted of (1) complete withdrawal of alcohol, (2) saline cathartics, (3) cold wet sheet packs during the period of active hallucinosis and excitement, (4) neutral continuous baths from 93 to 96 F., (5) electric light bath for the promotion of elimination, (6) fan douche and needle spray for their tonic effects, (7) high caloric diet and (8) occupational therapy. Under this regimen hallucinosis persisted between one and six days or an average of 3.2 days. Three patients, because of severe complications, remained for treatment for a period of several months, bringing the average period of hospital residence to 27.3 days. Five patients died. One death occurred in each decade between 20 and 70 years. Each of these presented a more serious type of complication on admission. Since the results compare so favorably with other series reported it is felt that hydrotherapy is an excellent means of treating delirium tremens.

Plasmodium Knowlesi Infections in Man.—Milam and Coggeshall inoculated thirty white and twelve Negro patients having dementia paralytica with Plasmodium knowlesi malaria for therapeutic purposes. In the thirty white patients, parasites

were first seen in blood smears as early as the third day and as late as the eighteenth day after inoculation and persisted for from three to fourteen days. Blood first proved to be non-infectious for rhesus monkeys as early as eighteen days and as late as 131 days after the original inoculation. After their blood was no longer infectious for monkeys, eighteen patients were reinoculated on twenty-three occasions, with time intervals of from thirty to 491 days after the original inoculation, and all were found to be immune. Negro patients were less susceptible to Plasmodium knowlesi infections than white patients; the incubation period was longer (from seven to twenty-seven days) and the duration of microscopically visible parasites ranged from two to eleven days. Their blood was infectious for monkeys as late as the thirty-sixth day and noninfectious as early as the twenty-eighth day after inoculation. Seven patients whose blood was noninfectious for monkeys were reinoculated at intervals of from twenty-eight to 107 days after the initial inoculation, and all were immune.

Atabrine as Prophylactic in Malaria.—Hill and Goodwin observed 1,646 persons for two years in order to determine whether or not a suitable method of drug prophylaxis was available for use in a highly malarious section of Georgia and Florida. In the area in which these studies were conducted, mosquito control measures were objectionable (the 16,000 acres was devoted to increasing and preserving wild game life for sport) and in many cases impossible, owing to the topography. Initial blood smears indicated a blood parasite index of 16.9 per cent. This has been reduced to 0.3 per cent over a period of two years. Atabrine proved to be the most successful prophylactic agent, although quinine seemed to exert a helpful influence in reducing the incidence of malaria. No toxic reactions to atabrine were observed. After the administration of both atabrine and plasmochin, the number of malarial carriers and cases exhibiting both gametocytes and schizonts was materially reduced. Because of the natural variations of malarial intensities caused by fluctuations in climatic conditions, these prophylactic experiments should always be continued over a period of several years to furnish the maximal amount of reliable information.

Environment and Tuberculosis in the Negro.—In order to overcome the differences of environment of the Negro as related to tuberculosis, Roth studied the figures from the United States Army and he believes that they equalize the environmental factor. They are made up of the absolute numbers and the rates for tuberculosis morbidity and mortality among enlisted men in the continental United States alone. For the period (1922 to 1936) under consideration the total white death rate is 0.24 per thousand enlisted men, while the Negro rate is 0.99. When this evidence is considered in conjunction with other environmental surveys and in view of the clinical and

pathologic differences which are to be recognized in the two races, environment cannot be held to explain the differences in susceptibility to the disease which the two races so generally manifest. The fact that tuberculosis, as it is handled by the army, accords so closely to the standard set in the Framingham experiment makes it possible for the author to generalize on the role which environment does play in tuberculosis in civil life. Diagnosis in the army is highly developed. The average death rate from tuberculosis in all troops combined for the fifteen years was 0.28 per thousand. According to the figures of the National Tuberculosis Association, the national death rate in 1927 for males in the age group corresponding roughly to that represented in the army (20 to 49 years) was 1.17 per thousand. A great deal of this difference is undoubtedly due to the fact that in the army a selected group of men is dealt with; but certainly environment can be held to be responsible for a considerable part of it. Even under optimal environmental conditions there would be the same difference in rates. A slightly greater percentage of Negroes might be expected to contract the disease, but a considerably greater percentage of them would die from it.

Carcinoma of Breast.—Shepherd concludes that chronic mastitis, stagnation, previous involutional or inflammatory changes and trauma are believed by many to be important predisposing conditions in carcinoma of the breast. Malignant tumor of the breast is especially prevalent in the fourth and

fifth decades of life; it is seldom found in persons less than 20 years of age, and about 1 per cent occur in men. Cystic disease is not believed to be a precancerous lesion. All single solid tumors of the breast should be removed for diagnosis. While the diagnosis of carcinoma can in the majority of cases be made from the gross tissue at the operating table, a competent pathologist with facilities for examining frozen sections should be available for the 10 or 20 per cent of cases in which this is not possible. Mammary cancer is found more often in married women than in unmarried women. Cancer of the breast seems to appear slightly earlier in those patients who are unable to meet the physiologic demands of pregnancy and latest in those who have never been pregnant. Cancer can be cured, but early diagnosis and appropriate treatment are absolutely necessary. Cases in which the lymph glands are involved decidedly outnumber those in which there is no such involvement. In the former group the mortality at the end of ten years is about four times that in the latter group. Definite metastases in the supraclavicular region are a contraindication to surgical treatment, as is also large extension to the axilla, because life is endangered and surgery in the minds of the public may be discredited. Continued education of the public is one of the best weapons in the fight against malignant tumors. Radical operation for cancer of the breast permits a number of different incisions but is commonly understood to demand the removal in one piece of the breast with all its skin, the pectoralis major and pectoralis minor muscles, the axillary contents (with the exception of the vein, the artery and the brachial plexus) and the deep fascia from the clavicle to the epigastrium and from the sternum to the latissimus. During the last decade patients have been coming to operation a few weeks earlier on the average than those of the previous ten years.

Leukocyte Exhaustion Following Surgical Procedures.

—Van Duyn has recently observed that, in association with a progressively downhill course after operation, examination of the blood frequently shows leukopenia, with a normal differential count and a marked shift to the left of the neutrophils. This picture signifies a wearing out of the leukopoietic power and offers an explanation of the patient's lack of response to therapeutic measures. He presents seven cases in which leukocyte exhaustion occurred. In all there was the characteristic leukopenia, with a marked shift to the left of the neutrophils. In four cases the degree of sepsis did not appear sufficient to have exhausted a normal leukopoietic power. It may be assumed, therefore, that in these cases the leukocyte reserve was at an abnormally low level before operation. The term "low leukocyte reserve" is used to designate this condition and to differentiate it from Doan's "low marrow reserve," in which agranulocytosis rather than leukocyte exhaustion develops. Leukocyte exhaustion occurs not only in cases of severe or prolonged sepsis but in cases of much milder strain and even in cases in which there is no strain at all. It should be considered as a possible complication of any surgical strain and its presence should be discovered early. This means that (1) leukocyte counts should be made at the time of admission and especially before operation for the detection of any immediate abnormality and for possible future comparisons, (2) counts should be made frequently when severe sepsis is present, in order to detect leukocyte exhaustion at an early stage, and (3) they should be made whenever a patient's condition becomes worse, especially postoperatively and in the presence of abdominal distention, even in the absence of demonstrable infection. The percentages of nonfilamented neutrophils should be determined at every count. The treatment of leukocyte exhaustion should probably be the same whether a severe or a mild strain is required to bring it about. In the cases reported, administration of liver extract, both orally and intramuscularly, and blood transfusions appeared to be of great value if administered early enough in the course of the leukopoietic breakdown.

Cobalt in Treatment of Milk Anemia.—Underwood and Elvehjem rendered fourteen rats anemic on whole cow's milk in the usual manner. At weaning they were divided into three groups for treatment; six were given milk ad libitum plus a daily supplement of 0.05 mg. of copper and 0.02 mg. of manganese together with 0.5 mg. of iron in the form of cobalt-free ferric chloride, three received the same treatment except that the iron salt was unpurified, and five rats also received the same treatment but in addition were given 0.1 mg. of cobalt a day in the form of cobalt chloride. The animals received the treatments for a period of three months, during which time frequent weighings and hemoglobin determinations were made. Cobalt determinations were carried out on the whole bodies of rats at birth and at weaning, on the livers of several of the experimental animals and on occasional samples of the milk as fed. It is concluded that iron, copper and manganese are the only minerals which must be added to milk for the normal growth and well being of the rat and that the small amounts of cobalt which contaminate almost all iron salts play no significant part in the treatment of milk anemia in the animal. The possible cobalt requirement appears to be less than 0.6 microgram daily.

Bromide Psychosis.—Curran discusses the histories of fifty (thirty-five women and fifteen men) patients with bromide psychosis admitted to the Bellevue Psychiatric Hospital. Although the presence of a bromide rash is stressed by many writers, such a rash was found in only nine of these patients. Pupillary changes were noted in practically all these cases, the most common observation being widely dilated pupils which

reacted sluggishly to light. Blurring of vision and diplopia occurred infrequently, although Craven lists these as typical changes. Weakness of convergence was found in a few cases. Only one patient complained of tinnitus. Seven patients had nystagmus; five were chronic alcoholic addicts, a sixth had a recent head injury with a period of unconsciousness and the seventh had a recent mastoidectomy with a purulent discharge from the left ear. It would appear probable, therefore, that nystagmus is not produced by the bromides but by other factors. Disturbances of speech were noted in practically all the patients; the speech is usually thick and indistinct. Tremors of the tongue, lips and fingers were present in all cases. A fever between 100 and 103 F. was present in most cases of delirium. Infections of the upper part of the respiratory tract were found in many patients. Tachycardia is present in most cases, the average pulse rate being from 120 to 140. Other frequent signs were fetid breath, coated tongue, conjunctivitis, impaired digestion, constipation, emaciation and vasomotor changes. Impotence in men and menstrual disturbances in women were occasionally found. There was one fatality, a patient dying with pulmonary edema within ten hours of admission to the hospital. The average duration of using bromides was several months. In thirty cases in which the blood was examined, from 55 to 500 mg. of sodium bromide per hundred cubic centimeters of serum was found. The average duration of hospital stay was approximately eighteen days. Thirty-three patients were discharged to the custody of relatives (of these, twenty-six had recovered from their psychosis and five others showed marked improvement), one was removed by relatives to be put in a private sanatorium, one was removed against advice by relatives, three were sent to private sanatoriums and twelve were committed to state hospitals. If a psychotic individual using bromides to excess does not show a marked remission in his mental symptoms within three to four weeks he is probably suffering from a more deep-seated psychosis than that merely produced by drugs. Treatment of bromide psychosis or intoxication consists of stopping the drug, forcing fluids and giving sodium chloride. Sedatives in all forms should be stopped and the excited patients should receive hydrotherapy in the form of continuous baths or wet packs. Cathartics and enemas should also be given to aid elimination. Bromide psychoses must be differentiated from dementia paralytica, alcoholic psychoses, encephalitis, multiple sclerosis and schizophrenia. When the bromide psychosis has cleared up a more deep-seated psychosis, such as manic-depressive psychosis, cerebral arteriosclerosis, involutional melancholia or schizophrenia, may be found. The majority of the patients in the present series used bromides following alcoholism. In some of the patients the bromide psychosis was superimposed on other mental diseases, including schizophrenia, manic-depressive psychosis and psychosis with cerebral arteriosclerosis. Bromides are eliminated slowly, they accumulate rapidly even in doses of from 45 to 60 grains (3 to 4 Gm.) daily and a delirium may occur within a few weeks even from ordinary therapeutic doses. Appropriate legislation should be secured to curb the indiscriminate sale of bromides to the public.

Antipyretic Action of Mercurochrome.—Emmett analyzes the forty intravenous injections of from 5 to 10 cc. of a 1 per cent solution of mercurochrome to thirty-four patients with acute pyelonephritis. The results substantiate the impression that acute pyelonephritis is the one condition in which the intravenous administration of mercurochrome may be expected to be effective. Its therapeutic value seems not to be that of eradicating the infection but rather of terminating the fever and ending the acute phase of the disease. Other chemotherapeutic agents must then be employed to sterilize the urine. This antipyretic action of mercurochrome may occasionally become an almost life saving procedure, as in a case in which septic fever threatens the life of a patient whose general condition is extremely poor. Mercurochrome often is of value especially when prostatic obstruction has caused severe disease of the kidneys.

Pulmonary Moniliasis.—Dearman points out that there have been observed on the Mississippi coast, in the past few years, at least six cases of primary pulmonary moniliasis. Their identification presented considerable diagnostic difficulty. The acute cases of the disease resembled acute bronchopneu-

monia in onset, physical signs and clinical course, while the chronic types simulated advanced pulmonary tuberculosis. A diagnosis of Monilia infections can be made only by repeated examinations of the sputum showing an absence of tubercle bacilli. The diagnosis of pulmonary moniliasis should be considered in any case of pulmonary disease in which the etiology is questionable.

Sulfanilamide in Oral Infections.—Lanier has used sulfanilamide as a routine in all oral infections except Vincent's stomatitis. In the outpatient clinic over a period of about six months, more than 100 cases in which teeth were extracted for far advanced pyorrhea were treated by inserting a tablet of from one-half to 5 grains (0.03 to 0.3 Gm.) of sulfanilamide into each socket. The same treatment was followed in extraction in more than 250 cases of chronic periapical infection. Smears taken from these sockets at the time of extraction showed many cocci present, while smears taken from twenty-four to forty-eight hours following treatment with sulfanilamide showed only a few organisms, and after three days no bacteria were present. In these cases there was a marked decrease in the usual after-extraction soreness, no pain and no dry sockets.

Systemic Pollen Reaction.—Because of the possible danger associated in the sudden introduction of pollen extracts subcutaneously, Credille devised an apparatus which consists of a rubber tourniquet 24 inches in length and 1½ inches in width for slow injection. At intervals of one-half inch, perforations have been made for the purpose of adjusting the device to any size arm. About 2 inches from one end of the tourniquet is anchored a metal, at the distal end of which is attached a metal spring clamp for the purpose of holding a tuberculin syringe. The apparatus is adjusted to the upper part of the arm, and the tourniquet is tightened for a minute. The needle is then introduced subcutaneously at the outer aspects of the arm, 1½ inches below the tourniquet. The piston is withdrawn slowly once or twice and if there is no evidence of blood the tourniquet is released enough to permit venous flow, but it is retained on the arm sufficiently tight to support the apparatus for holding the syringe. The syringe is then clamped and held in position while a drop of the antigen is injected at intervals of one minute for five minutes. If there is no sign of reaction, the remainder of the material is injected. At the end of six minutes if there are no signs of general reaction the syringe and apparatus are removed. During the time of injections all patients are instructed to report any subjective symptoms that may develop, such as itching of the palms, generalized pruritus or tingling of the tongue. All patients should remain in the office for at least fifteen minutes following injection.

Gonorrhea and Hydrochloric Acid.—About three years ago Verdier began to use hydrochloric acid intravenously and intramuscularly in the treatment of gonorrhea in adults and children. Of the many thousands of injections (several thou-

sand cases) given there has not been a failure of cure or an unfavorable reaction. That the acid promotes an immediate response from the leukocytes can be easily demonstrated, thousands of comparative counts have been performed and uniformity was demonstrated. In acute uncomplicated gonorrhea, the initial intravenous injection is 10 cc. of a 1:500 dilution of hydrochloric acid in distilled water. This is repeated daily for about ten consecutive days, when the clinical symptoms are generally such that the interval between injections may be lengthened to two or three days for the period necessary to establish a proved cure. In subacute or complicated cases of gonorrhea the injections are given at intervals of two days until improvement begins, and then the periods are lengthened. The most impressive feature in connection with this form of therapy is the quick response of the subjective symptoms in the patient combined with a feeling of general bodily stimulation. Urinary distress and associated symptoms disappear with remarkable rapidity, and it is no unusual experience to see copious discharges lessen within forty-eight hours. For those unskilled in intravenous methods, an intramuscular injection of hydrochloric acid may be used; the strength generally used with good results was 2 cc. of a 2 per cent solution of hydrochloric acid in sterile water, with a 1 per cent addition of butyn. This is an almost painless procedure when the injection is given in the upper outer quadrant of the buttock with a keen needle of sufficient length to reach the belly of the muscle.

Acute Obstruction of Bowel.—McGillivray reports a case of high obstruction of the ileum (old adhesions following operation), one proved to be a Meckel's diverticulum, one of simple constriction of the ileum at the middle portion (high attach-

ment to stomach region) and one due to the folding of the ileum near the lower portion, due to old adhesions from drainage of an appendical abscess. The first patient died but could probably have been saved by early operation had it been permitted. Suction, as advocated by Wangenstein and others, seems to be a distinct advance in the early treatment of intestinal obstruction. It gives great relief and gives a little time to prepare the patient and decide on the type of operation necessary. It has been proved of inestimable value in postoperative treatment, including ileus and minor obstruction.

Gastrointestinal Expressions of Avitaminosis.—Musser and Sodeman maintain that subclinical expressions of scurvy, beriberi and rickets are common and that expressions of borderline vitamin deficiency are encountered in all fields of internal medicine and particularly in the realm of gastro-enterology. There is between the deficiency necessary for the development of the full blown picture of disease and the intake optimal for the body a broad range in which the symptomatic expression is not typical or is nonspecific. Protean and diverse are the symptoms of the alimentary tract arising as a result of inadequate or minimal intake of the vitamins. The dietary flaws of the alimentary tract are discussed under three headings: the specific deficiencies, chronic dietary deficiency and conditioned deficiencies. The clinician in the management of patients suffering from rather vague and indeterminate symptoms, notably those which may be labeled dyspepsia or dyspepsia symptoms, should bear in mind that they may result from a diet which on superficial examination seems to be adequate but which actually is substandard.

Osteolytic Osteogenic Sarcoma.—McReynolds states that in the entire group of 131 cases of osteolytic sarcoma recorded in the surgical pathologic laboratory of the Johns Hopkins Hospital there was a total of 117 cases in which the age was recorded. Fifty-six patients were from 11 to 20 years of age, 16 per cent were from 21 to 30, 8.5 per cent were in each of the next three decades, only one patient was less than 10 years of age, and seven were more than 60 years of age. The bones most often involved were in their order of frequency lower part of the femur, upper part of the tibia, pelvis, humerus, middle portion of the femur and lower part of the tibia. Among these patients were eleven who lived longer than five years after treatment was instituted. Three of these cases formerly believed to be osteolytic sarcoma were excluded because two had a marked resemblance to sarcoma of the nerve sheath and the other presented the histologic structure of synovial sarcoma. These patients were alive eleven, ten and twenty-eight years after radical resection or amputation which showed a destructive lesion in the involved bone. Of the eight remaining patients, five lived approximately ten years or longer and three died with metastasis at six, seven and seven and one-fourth years, respectively, after operation. The average duration of life was 10.3 months in the ninety-nine patients followed for five years after the primary treatment. Osteolytic sarcoma occasionally arises in a benign giant cell tumor, and this may account for the reports that some giant cell tumors metastasize fatally. Primary amputation well above the location of the tumor or radical resection if the diagnosis is confirmed is still the treatment of choice. The fact that minute deposits of tumorous tissue are often present in the marrow spaces at some distance from the gross lesion accounts for the frequent recurrence in the amputation stump.

Gout in Women.—Statistics show that 90 per cent of gout occurs in men, but Thomson points out that, as it is more likely to be overlooked in the more chronic and atypical forms (diagnosed as atypical rheumatoid or osteo-arthritis) in which it so often occurs in women, its incidence in women is probably higher. Though acute gout in its classic form does occasionally occur in women, it appears to be decidedly uncommon. In the great majority of cases gout occurs in women in its more chronic form. Chronic gout in women frequently presents a superficial resemblance to rheumatoid arthritis, particularly if the patient presents herself with one or more swollen and painful interphalangeal joints and is of the thin, debilitated type commonly associated with the latter disease. Instead of the diffuse fusiform periarticular swelling of rheumatoid arthritis, the outline of the joint is usually more irregular and the characteristic muscular wasting and deformity of rheumatoid arthritis are absent. If, on the other hand, the patient presents evidence of osteo-arthritis in the form of Heberden's nodes or a creaking knee with osteophytic deposits, the gouty lesions are likely to be attributed entirely to degenerative changes. Mixed forms of arthritis are not uncommon. Gout may occur in an osteo-arthritic joint as in any other, and conversely osteophytes frequently occur as a late result of gout. Another type of case in which the question of gout often arises is that of the woman presenting the signs and symptoms diagnosed as climacteric arthritis. The easier way of life, diminution of physical activity and tendency to indulge in more and richer food—which determine the onset of gout in middle aged men—apply equally or even more to women, in whom the climacteric implies a profound change in the physiologic "pattern." It is in the overnourished, florid type of women, the habit of body traditionally associated with gout, that climacteric

arthritis is especially prone to occur. Quite apart from the doubtful question as to whether climacteric arthritis is in itself an expression of gout, patients who suffer from villous arthritis of the knees commonly develop mild transitory attacks of swelling and tenderness in other joints. Here again one may be dealing with a condition of "mixed" arthritis, and the term "rheumatoid gout" does convey an adequate and reasonable description of the clinical aspects of such a case.

Pulmonary Tuberculosis in Diabetes.—Gloyne reviewed the postmortem records of the London Chest Hospital, which is primarily concerned with the treatment of intrathoracic disease, and found twenty-one deaths (0.75 per cent) from diabetes in 2,826 necropsies (1,138 with active tuberculosis and 1,688 with nontuberculous diseases) between 1888 and 1937. Of the twenty-one patients with diabetes, four were not associated with tuberculosis and a fifth had only calcareous tubercles with puckering of the lung apices. The remaining sixteen had active pulmonary tuberculosis and comprised 1.4 per cent of the 1,138 necropsies with active tuberculosis. The majority of the patients were of the middle-age group. The type of tuberculous lesion found was that of excavation with extensive caseation, often pneumonic or bronchopneumonic in distribution. The common sequela of tuberculous laryngitis and enteritis was not encountered. No tuberculous foci were found elsewhere in the body (including the pancreas), except one example of miliary tubercles in the kidney, evidently a terminal lesion. Only one instance occurred in which there was any sign of quiescence. No significant differences were noted in the necropsies of the preinsulin and insulin periods. Obviously the diabetic patient is exposed to the same risks of infection as the rest of the population. No figures appear to exist for England to confirm or refute the clinical impression that the diabetic patient is prone to tuberculous infection, but the extensive American figures on the whole support the view.

*Cutaneous and Conjunctival Diphtheria. H. R. Rogers.—p. 283.

Cutaneous and Conjunctival Diphtheria.—Rogers presents eleven cases of cutaneous or conjunctival diphtheria which occurred within the last four months of 1937. The liability of these rarer forms of diphtheria to be multiple and to be associated with other conditions (e. g., streptococcal infections) is

shown. The importance of bearing in mind the possibility of diphtheritic infection in cases of conjunctivitis and impetigo which do not readily clear up with local treatment is suggested. Nine of the eleven patients recovered. The cause of death in each of the fatal cases was an associated streptococcal condition. In cutaneous or conjunctival diphtheria toxemia is not a marked feature; and the lesions, however long standing, quickly heal after the administration of antitoxin. These rare forms of diphtheria were present on admission in seven patients in conjunction with concurrent scarlet fever, erysipelas or measles. In none of the cases here recorded was the predominant or associated infection contracted after admission to hospital. The cutaneous or conjunctival diphtheritic condition was the sole infection in only two patients. In the five cases of cutaneous diphtheria the association of impetigo of the face or limbs with the diphtheritic or erysipelatos condition led to the swabbing of the cutaneous lesions. Of the six cases with conjunctival lesions, five were bilateral.

*Vomiting in Diabetic Children. W. W. Payne.—p. 195.

Dysentery Due to Bacterium Dysenteriae.—Evans discusses two epidemics and sporadic cases of dysentery at the North Wales Counties Mental Hospital, Denbigh. The Schmitz bacillus is believed to have been the causative organism. In 1935 there were thirty-five cases and in 1938 there were 129 cases. In the 1935 epidemic an organism having the morphologic and biochemical characteristics of Bacterium dysenteriae Schmitz was isolated from twenty-one of twenty-nine cases examined. In the 1938 epidemic the Schmitz bacillus was identified by its serologic as well as its morphologic and biochemical characteristics and was found in thirty-nine of sixty-two cases examined. In the interval between the two epidemics a bacillus conforming morphologically and biochemically to the Schmitz bacillus was isolated from twelve sporadic cases of dysentery among women. Of these, nine occurred within a month and constituted a minor epidemic. In identifying the Denbigh strain of the Schmitz bacillus, Boyd's 214 serum was used. The serum is obtained by inoculating a rabbit intravenously with a killed suspension of this strain. The investigation into these epidemics supports the position of Bacterium dysenteriae Schmitz as a pathogen.

Vomiting in Diabetic Children.—According to Payne, in a typical attack of vomiting in diabetic children abdominal pain with nausea or loss of appetite are the first symptoms, and later on there is vomiting and perhaps headache. The child may be either flushed or pallid; the temperature is usually normal but may be slightly raised. After a few hours the condition may clear up and the appetite return, but often the vomiting persists and the progress now depends on the treatment. If nothing is done, and especially if no insulin is given, signs of ketosis develop, such as rapid respiration and drowsiness, and diabetic coma supervenes. Diarrhea may sometimes be an important symptom, but such cases do not progress to coma. The condition closely resembles recurrent or cyclic vomiting (often misnamed "acidosis" attacks) which occur in nondiabetic children. Usually in cases of vomiting not due to acute infections there is either a history of nervous excitement or a history of preceding hypo-

glycemia or at least of greater freedom from glycosuria. A possible explanation of this sequence of events is as follows: The initial hypoglycemia stimulates the secretion of epinephrine, which presumably has the effect of liberating dextrose from the liver and thus raising the blood sugar. It is therefore not improbable that in some more susceptible patients the action of the epinephrine on the alimentary tract will be apparent. Any other effective stimulus to the oversecretion of epinephrine can give rise to similar effects, thus accounting for attacks produced by excitement, shock or fever. When the oversecretion of epinephrine ceases, these disturbances disappear and the patient recovers from the attack without further complications. If, however, the child's store of glycogen is low, a carbohydrate starvation develops, since no food is being absorbed from the intestine and all the available glycogen has been used up by the epinephrine. Fat unbalanced by carbohydrate must now be used, and this causes a production of ketone bodies and a lessened effectiveness of such insulin as is available (Himsworth, 1934), leading to formation of ketone in still greater amounts. The increased ketonemia will cause further vomiting. The condition now resembles that of untreated diabetes. In the early stages the treatment is simple. In the hypoglycemic variety administration of sugar at the very commencement of the attack will abort it by raising the blood sugar and stopping further secretion of epinephrine. If the condition has advanced beyond this stage it is sometimes sufficient to stimulate the stomach to function normally by gentian and sodium bicarbonate. If this is unsuccessful and nausea persists or vomiting occurs, it is necessary to give sugar together with insulin. An injection of from 20 to 30 units of insulin is usually needed and the sugar should exceed 1 ounce (30 Gm.). The sugar and insulin may be repeated at intervals of four hours if necessary. It is vitally important that sugar should be absorbed. The treatment of the later stages is that of diabetic coma.

*Id.: II. The Antiscorbutic Activity of the Hunan Kwang Chü. T. F. Su and T. P. Tu.—p. 44.

Hunan Citrus Fruits.—Su and his co-workers analyzed five species of Hunan citrus fruits for their ascorbic acid content. The determination of the vitamin C content of the juice revealed that the Hunan Kivang Chü orange and two species of pemulo are rich in ascorbic acid. For its high vitamin C content, low price and convenience for household use and infantile feeding the Hunan Kwang Chü orange is to be highly recommended. The antiscorbutic activity of the juice of the Hunan Kwang Chü orange was comparable to that of the Sunkist orange and that of the real Kwang Chü orange.

*Role of Liver in Modification of Proteins in Patients with Suppurations: Hemoclastic Shock. I. Blitstein.—p. 145.

Effect of Liver on Proteins in Suppurations.—Blitstein points out that the liver plays an important part in the metabolism of proteins. The existence of a proteopexic function of the liver has been demonstrated by Widal and his collaborators. These authors observed in dogs with Eck's fistula, after a meal rich in protein, a shock which manifested itself in a reduction in the blood pressure, leukopenia, inversion of the leukocytic formula, diminution of the refractometric index and a reduction in the coagulability of the blood. The same phenomena were produced following the injection into a vein of the general circulation of blood withdrawn from the portal vein after a meal rich in proteins or following the injection of peptone into the peripheral circulation. When products of the decomposition of protein are resorbed in the intestine they are diverted to the liver. When the liver is impaired this function is weakened and the foreign proteins pass through into the general circulation and provoke the same changes in the blood as do the experiments cited. Widal and his collaborators suggested a test for the detection of the proteopexic insufficiency, namely the digestive hemoclasia reaction (hemoclastic crisis). According to these authors this test is frequently positive in hepatic insufficiency. However, it has been found that the test is not strictly specific for proteins, because positive reactions can be produced also with fats or carbohydrates. Moreover, the reaction is often positive in infectious diseases and negative in patients with hepatic disorders when they have disturbances which are accompanied by leukopenia; in these cases even a leukocytosis may develop. Widal pointed out that after the injection of peptones there results an immunity of twelve hours' duration and others demonstrated that the same immunity can be observed in the course of infections which are accompanied by a destruction of albumins. This immunity can be detected by Umber's test. Umber demonstrated that rectal lavage with milk produces a hemoclastic shock even in normal subjects, because the milk is resorbed by the blood without passing through the liver. Thus Umber's test must produce positive reactions in all persons except those who have been immunized. Immunity against hemoclastic shock is observed under the following conditions: (1) for a period of from three to four weeks after an injection of serum, (2) in infections that are accompanied by high fever and (3) in all forms of leukopenia. Blitstein studied hemoclastic shock sixteen times according to Widal's technic (in fourteen patients, twelve of whom had suppurating infections and two had hepatic disorders) and three times according to Umber's technic. In seven patients with suppurations the digestive hemoclasia was positive, in three doubtful and in two negative. In the latter two, Umber's test revealed that they were immunized. Three negative results were observed in two patients who previously had had a positive hemoclasia. In one case the negative result was explained by a leukopenia.

*Syndrome of Hyperfolliculinism. J. Varangot.—p. 1180.

Hyperfolliculinism.—Varangot applies the term syndrome of hyperfolliculinism to disturbances that are caused by the presence of excessive quantities of estrogen. Discussing the experimentally induced syndrome of hyperfolliculinism, he first reviews animal experiments made by various investigators and then shows that the syndrome can be induced in castrated non-hysterectomized women by the injection of large doses of the estrus-producing substance. Moreover, the syndrome has been

known to develop in impuberal girls in whom an existing gonococcal vulvovaginitis was treated with injections of estrogen. After discussing the clinical manifestations and the humoral aspects of the syndrome that is induced by an excess of estrogen, the author gives his attention to its causes. In the conclusion he says that a hyperplasia of the endometrium constitutes the most definite sign of the existence of a hyperfolliculinism; that is, the biopsy of the endometrium reveals the presence of excessive quantities of estrogen. The determining causes of the syndrome are not all known as yet. Besides lesions of the folliculosecretory parenchyma of the ovaries, there must exist functional disorders of the ovary without visible lesions and disturbances in the metabolism of the estrogenic bodies, which lead to the status of hyperfolliculinism. The inadequacy of the methods of quantitative investigation of the ovarian function does not yet permit an explanation of the mechanism and pathogenesis of the disorder.

Three Fractures of Vertebral Column Treated by Infiltrations of Procaine Hydrochloride. A. Jung and N. Christéas.—p. 458.

Modifications of Metabolism by Operations.—In order to throw light on the modification of the metabolic processes by surgical intervention, Delrez studied subjects who were comparatively young and healthy and who had a noninfectious, benign surgical disorder that could be treated under local anesthesia. On the basis of his investigations he reaches the following conclusions: 1. The influence exerted by an operation on the basal metabolism is neither considerable nor uniform. 2. Surgical treatment brings about an increase in the nitrogenous metabolism, which becomes manifest in hyperazotemia and hyperazoturia. Abundant hydration of the subject operated on usually diminished the hyperazotemia, although its effect on the hyperazoturia is practically nil. 3. An operation is followed by a hypochloremia, which the ingestion of chlorides is incapable to combat efficiently because the ingested chloride is rapidly eliminated in the urine. There is no apparent relation between hyperazotemia and hypochloremia; the treatment referred to as "rechloridation" seems to act on the humoral status of the person who has been operated on only in the proportion in which it utilizes the water of the organism. 4. The renal function, estimated by the method of Rehberg, behaves in the following manner: The function of glomerular filtration is practically unchanged, whereas the tubular function of reabsorption varies; (a) chloride is reabsorbed with great intensity; (b) water is reabsorbed in variable proportions, probably according to the state of hydration of the tissues; (c) the reabsorption of urea varies in the same manner as that of water; this greatly influences the excretion of the nitrogenous waste products and the degree of azotemia. It appears that hydration has an important part in the prevention and the therapy of postoperative azotemia.

Abacterial Meningitides.—Fanconi says that the benign, so-called aseptic or, better, abacteriologic meningitides are important in the differential diagnosis of the preparalytic meningitis of acute anterior poliomyelitis. He shows that knowledge of the course of the completely developed poliomyelitis is the most important factor in the correct diagnosis and he describes a typical case. He points out that formerly a differentiation was made merely between the preparalytic and the paralytic phase but that two phases can be distinguished within the preparalytic one, namely a purely meningitic one

and the preparalytic one, in the restricted meaning. The meningitic phase is characterized by headaches, backaches, rigidity of the neck, Kernig's sign, increase in the reflexes and so on. The preparalytic phase, in the restricted sense of the term, begins when symptoms of adynamia, weakening of muscular power and of the reflexes are added to the meningitic symptoms. During the meningitic phase the inflammation is restricted to the meninges; during the preparalytic stage an inflammatory edematous swelling develops in the gray matter of the anterior horn, and during the paralytic stage the irreparable neuronophagy of the ganglion cells of the anterior horns begins. In many cases the poliomyelitis fortunately does not reach the paralytic stage. Those cases which are arrested in the meningitic or in the preparalytic stage the author regards as abortive. In reviewing case histories of former years he finds that such cases in which paralytic symptoms did not develop were often diagnosed as aseptic meningitis, but he thinks that many were abortive cases of poliomyelitis. He believes that, although typical poliomyelitis usually develops during the summer months, abortive cases may occur the year round. However, although he thinks that many cases that have been diagnosed as aseptic meningitis were really atypical cases of poliomyelitis, he does not deny the existence of a benign lymphocytic meningitis as a disease *sui generis*. He describes a case in which the diagnosis of benign acute lymphocytic meningitis was justified because there were no preparalytic symptoms, there was no dromedary curve and the suddenly appearing meningitic symptoms were too severe for a poliomyelitis. However, he does not consider it justified to regard the dromedary curve as characteristic for poliomyelitis and as an aid in the differential diagnosis, because there is at least one form of abacterial virus meningitis, namely the disease of swineherds, in which the dromedary curve is likewise observed. To be sure, the dromedary type of the fever curve in the disease of swineherds differs somewhat from that in poliomyelitis in that in the first disease the stage of general infection is the severest and longest and the meningitic stage is short and the fever not so high.

Tubercle Bacilli in Gastric Secretion and Feces in Tuberculosis.—Monaco and Ruggiero investigated the gastric secretion and the feces of seventy children, ranging in age from 2 to 12 years, who presented various forms of pulmonary tuberculosis. Petragiani and Ogawa's technics were used in making the cultural studies. The biologic tests were carried out on guinea pigs. Tubercle bacilli were identified in the gastric secretion in twenty-three cases by the biologic and cultural method and in four by microscopic examination of the enriched secretion. They were identified in the feces by the cultural and biologic method in nine cases. The authors point out the importance of the application of the method for an early diagnosis of pulmonary tuberculosis, for the prevention of the disease and also in following the evolution of the disease.

Asystolia in Nurslings.—Bonaba and Saldún de Rodríguez report seven cases of primary acute insufficiency and dilatation of the heart in children. Five were nurslings and two were

young children. The authors say that the syndrome develops suddenly in either eutrophic or dystrophic infants and children apparently in normal health. There is no fever. The symptoms are prostration, depression, vomiting, spasmodic cough, dyspnea, cyanosis, increase of the cardiac volume from acute dilatation of the heart, hepatomegaly, edema, anasarca and ascites. The condition must be differentiated from bronchopneumonia, idiopathic hypertrophy of the heart and primary pericarditis. The etiology is unknown. The treatment consists in early bleeding and prolonged administration of digitalis and of other cardiac tonics. Complete recovery may take place or there may be either a clinical recovery with persistence of the increased volume of the heart or with dilatation of the organ or a transient recovery with recurrences. When the disease follows a fatal evolution, peripheral edema, congestion and edema of the lung, ascites and anasarca develop early. The anatomic study shows dilatation of the heart and visceral congestion and edema of the cardiac type. Hypertrophy and malformations of the heart or lesions of the valves do not exist. The structure of the cardiac muscle is normal on microscopic study.

Para-Apical X-Ray Shadows.—Heidenreich and Joselevich review the different theories on the origin and characteristic aspects of the apical triangular shadows which appear in roentgenograms which are taken in the frontal position in patients with cardiovascular diseases. It has been stated that shadows with neat contours show abnormal ligaments of bands of fibrous tissue from the parietal pericardium to the cupola of the left hemidiaphragm, whereas those with rough contours show local accumulation of fat. The authors saw the shadow with smooth contours in frontal roentgenograms of four patients in the course of cardiovascular diseases. They found at necropsy that the shadows were made by accumulation of fat around the apex of the heart. The fat accumulates in the pleural tissue which is in contact with the pericardium and it forms a piece of fat similar to a small tongue. The appearance of the shadow in the roentgenogram depends on the size of accumulation of fat in relation to the enlargement of the heart.

- Changes of Calcemia After Hysterectomy Alone or in Association with Removal of Ovaries in Fibromatosis of Uterus. B. A. Macola and P. Martínez Esteve.—p. 195.

Minerals in Blood of Children with Typhoid.—Valdés and his collaborators made determinations of the minerals in the blood of sixty-one children with typhoid, ranging in age from 2 to 12 years. Clark and Collip's method was used for determining the calcium in the blood, Bell and Doisy's for that of inorganic phosphorus, and Bell-Doisy-Briggs' and Kramer-Tisdall's for those of magnesium and potassium and sodium, respectively. The amount of sodium, potassium and magnesium in the blood are normal at the height of the disease and increased in convalescence. The amount of calcium and phosphorus is diminished at the height of the disease and normal in convalescence. In the course of typhoid with cardiovascular complications the amount of sodium in the blood is higher than normal, that of potassium is lower than normal, calcium and phosphorus are still lower and magnesium does not change. The minerals in the blood do not change in the course of typhoid with intestinal perforation.

- Treatment of Fractures of Neck of Femur. S. Becker.—p. 535.

Migration of Tetanus Toxin.—Bromeis points out that in the treatment of tetanus the quantity and especially the duration of the administration of antitoxin are not uniform. He thinks that this is due to the fact that, although the incubation period is known, it is not known how rapidly the tetanus toxin migrates. The entire period of incubation can be divided into four stages: during the first one the toxin is formed at the port of entry; during the second stage the toxin migrates from this site to the regional nerve; during the third stage it travels along the nerve to the central nervous system and during the fourth stage it accumulates and then penetrates into the cells of the central nervous system. In order to determine the length of these different periods, the author made experiments on guinea pigs and rabbits. Summarizing his observations, he says that the toxin travels in the lymph channels of the tissue, from the site of formation to the regional nerve, at the rate of about 1 cm. an hour; the passage along the nerve to the spinal cord is somewhat more rapid. The latter requires in rabbits twelve hours, with a total incubation period of from forty-two to forty-eight hours; in guinea pigs about six hours, with an incubation period of from eighteen to twenty-four hours. The longest part of the incubation period, more than half of the time, is required for the accumulation around and entrance into the cells of the spinal cord. The migration from the depot of the toxin to the nerve requires only a small part of the period of incubation. The conclusion at which the author arrives on the basis of these observations is that in human subjects too the time during which the administration of tetanus antitoxin promises results is relatively short. For this reason all antitoxin should be administered on the first day or on the first two days.

Cholangiography During Operation.—Hultén defines cholangiography as the roentgenologic visualization of the biliary passages. To perform a cholangiography the contrast fluid can be introduced either through an external biliary fistula or through a surgically introduced choledochus drain. This procedure is designated by the author as secondary cholangiography. He shows that cholangiography can be performed also during the operation; that is, following the exposure of the bile passages, by means of direct injection of the contrast fluid into the bile passages. To this method he applies the term primary cholangiography. After pointing out that Mirizzi was the first one who performed and described this primary cholangiography, the author says that during the last year he himself performed primary cholangiography systematically in all operations on the biliary passages. He says that a water soluble contrast medium should be used which mixes with the bile. The roentgenogram must be sharp and clear, because otherwise defects in filling are readily overlooked. In order to obtain clear pictures, respiratory movement must be avoided during the roentgenologic exposure; the patient must hold his breath. To do this the patient must be awake, that is, the operation should be made under spinal or splanchnic anesthesia. The mattress of the operating table has an opening for the insertion of the film holder. The author describes the course of the operation and of the primary cholangiography and he reproduces some of the roentgenograms which he obtained by means of the primary cholangiography. He discusses the conditions that influence the passage of the contrast medium through the duodenal portion of the choledochus. The possibility of a differentiation by primary cholangiography of a pathologic spasm of the sphincter from an accidental contraction he regards as slight. He points out

further that, as the result of duodenal peristalsis, the papillary region may lack clearness in the roentgenogram. For this reason he recommends a cautious probing and dilation of the duodenal portion of the choledochus whenever the contrast medium has not freely entered the intestine. He concludes that primary cholangiography is for him an indispensable aid in operations on the biliary passages. It is of great value in determining the presence or absence of calculi in the choledochus and permits a definite differentiation between an obstructing hindrance and an organic stenosis.

Beta-Phenylisopropylamine Sulfate.—Bahnsen and his associates point out that the administration of large doses of ephedrine to patients with asthma occasionally causes insomnia and motor unrest. However, not until 1930 was it suggested that this action of ephedrine could be utilized in the treatment of narcolepsy. Benzedrine (beta-phenylisopropylamine), a substance closely related to ephedrine, was found even more effective in the treatment of narcolepsy and it was discovered also that, besides counteracting the uncontrollable desire to sleep in patients with narcolepsy, it influenced normal persons not only by acting on their sleep but also by producing a noticeable euphoria, reducing tiredness and increasing energy and the capacity to work. This amine was soon used widely by normal persons, particularly by those who had to do strenuous mental work. The authors decided to study certain aspects of the use of benzedrine and of related substances. They aimed to determine to what extent the supposed favorable actions were merely imagination. Moreover it is known that, whereas some persons are enthusiastic about the effects, others assert that they experience no effects, while still others complain of a number of unpleasant symptoms, such as sweating, attacks of chills, palpitation of the heart, and headaches. Studies were made on several hundred healthy men and women. Some of these received no medication; a second group was given inactive tablets (containing 0.1 mg. of quinine sulfate), which were of the same shape, size and taste as the tablets of beta-phenylisopropylamine sulfate; the latter were given to the third group. Summarizing their observation, the authors say that they observed the same symptoms that had been detected by previous investigators. That the effects were not merely imagined was proved by their absence in the persons who, although unaware of the fact, had received control tablets. Some of the symptoms appear in complexes which are relatively independent of one another. There are cerebral and peripheral complexes. The cerebral ones stimulate activity and influence the mood in a favorable manner. Of the peripheral symptoms, cardiac palpitation, muscular tension and tremor of the hand concur so frequently that a common cause may be assumed. However, the different temperature sensations, the feeling of dryness in the mouth and throat and the lack of appetite appear more independently. If the cerebral symptoms predominate, the effect of the drug is usually experienced as pleasant, whereas in cases in which the peripheral symptoms predominate the effect is experienced as unpleasant. However, the number of cases in which the indisposition reaches such a degree that the drug impairs rather than stimulates activity is small (3 per cent). Discussing the problem whether healthy persons should be permitted to use beta-phenylisopropylamine sulfate temporarily in order to counteract sleepiness during times when intensive work is required, the authors say that the work does not suffer and the persons are capable of manipulating precision instruments or driving a motorcar. In some persons the drug may cause unpleasant effects and in persons who have never experienced its effects on themselves.

the use should not be permitted if the work they have to do is of great importance. The authors emphasize the necessity of combating the belief held by many lay persons that the use of the drug can serve as a substitute for physiologic rest. They advise against its use in cases in which the intensive work extends over a longer period or in which there is no insurance of an adequate period of rest before as well as after the exertion.

Organization of Traumatic Station in Medium Sized Hospital. K. Czyżewski.—p. 632.
*Action of Vitamin B₁ on Thyroid Gland. B. Giedosz.—p. 635.

Action of Vitamin B₁ on Thyroid.—Giedosz administered subcutaneous injections of pure crystals of vitamin B₁ to guinea pigs in order to test its influence on the thyroid. He selected female guinea pigs weighing from 210 to 275 Gm. and divided them into two groups. To group 1 he injected 1,000 international units (2 mg.) daily for seven days, which amounted to 14 mg., or 7,000 international units of vitamin B₁. In one case it was administered for fourteen days (32 mg.). The animals in group 2 each received 0.01 Gm., or 5,000 international units of vitamin B₁ daily; that is, five times the amount given to group 1. One guinea pig was injected with 0.06 Gm. (30,000 international units) and the rest with 0.07 Gm. (35,000 international units) for seven days. After twenty-four hours the animals were killed; the thyroids were resected, prepared and examined. The animals had been well fed but kept in a well lighted room, each separately and at room temperature. The microscopic picture of the segments of the thyroids of guinea pigs after the subcutaneous injection of vitamin B₁ shows evidence of stimulation of the thyroid. Administration of vitamin B₁ in large doses in different stages of hyperthyroidism is not necessary. In a diseased thyroid a level intake of vitamin B₁ must be aimed at. Vitamin B₁ does not exert any influence on hyperthyroidism in guinea pigs nor is vitamin B₁ antagonistic to thyroxine, he believes.

Gonadotropic and Estrogenic Substance in Urine.—Kjelland-Mørdré made determinations of gonadotropic and estrogenic substance of the urine in six cases of normal pregnancy, seven of spontaneous abortion without surgical intervention and thirty-six of induced abortion performed for various medical indications or of spontaneous abortion in which operative treatment was administered because of hemiorrhage. He finds no evidence that artificial abortion causes disturbances of any importance in the endocrine balance of the organism, with regard to menstruation or otherwise, and concludes that Sersdjukow's view of the injurious effect of induced abortion on the endocrine glands cannot be generally accepted for normally developed women, in whom such effects are the exception.

Electrocardiographic Changes After Thyroid Medication.—Rasmussen says that in his first patient, with myxedema and a characteristic abnormal electrocardiogram, the electrocardiograms became normal after treatment with thyroid. In three of five patients with hypothyroidism the T waves were abnormally low in lead I or leads I and 2; after treatment with thyroid they became normal in two cases and improved in the third. Four of six patients with obesity and normal basal metabolism had low T waves in lead I; after two or three weeks' thyroid treatment the T waves were normal in two cases, improved in one and unchanged in one.
